A further report from the same committee on the examinations of the Egyptian Medical School at Cairo was received from Dr. T. D. Acland, who was appointed by the two Royal Colleges to visit and inspect the examinations. A cordial vote of thanks was given to Dr. Acland for his "interesting and valuable report."

NOTICE was officially given in this journal of the prizes to be awarded by the Council of the College. These are the Quinquennial Cartwright Prize; the next award will be for the five years ending December 31st, 1910. The prize consists of a bronze medal and an honorarium of £70. The subject for the essays to be submitted in competition for this prize is "The Prevention of Dental Caries." The subject for the Jacksonian Prize for the year 1908 is "The Prethology and Treatment of those Conditions and Diseases of the Colon which are relievable by Operative Measures." Candidates must be Fellows or Members of the College, and Essays must be delivered at the College not later than December 31st, 1908. Further particulars may be obtained on application to the Secretary of the College.

The Royal Visit to Tottenham Hospital.

THE new wards and the operating theatre of the Tottenham Hospital were formally opened by the Prince and Princess of Wales on May 7th. Their Royal Highnesses were received by H.R.H. the Princess Louise (Duchess of Argyll), the President of the Hospital; Sir Francis Cory-Wright, Bart., chairman; Lady Cory-Wright; the Right Hon. the Earl and Countess of Jersey; Sir James and Lady Reid; Mr. John Langton, F.R.C.S.,; the Director (Mr. F. W. Drewett), and the Matron (Miss E. Margaret Fox). The royal party then proceeded directly to a marquee erected in the grounds of the hospital where a concourse of about two thousand people had assembled. After a brief dedicatory service by the Ven. Archdeacon of London, representing the Bishop of London, the Chairman read an address of welcome in which he alluded to the visit paid to the hospital for a similar purpose by Their Majesties, when Prince and Princess of Wales, just twenty years ago. The Prince of Wales in replying, expressed his pleasure at being present, and amid loud cheers announced that in future the hospital should be called "The Prince of Wales' General Hospital, Tottenham," and that he was proud to think that it should bear his name. His Royal Highness then declared the new buildings to be open. A list of special contributions to the hospital was then read by the director, after which the Princess of Wales received a large number of purses. The amount thus realised was £4,000. A certain number of presentations were then made, after which the royal party inspected the hospital, and before leaving their Royal Highnesses graciously signed the visitor's book. The hospital and grounds were then thrown open for the inspection of the invited guests, among whom were Sir Henry Burdett, the Chief Rabbi, Dr. Alder, the Warden of the Drapers' Company, Mr. Ernest Gardiner. M.P., Mr. Herbert Nield, M.P., the Mayors of Hackney and Stoke Newington, Mr. Joseph Howard, Mr. Henry Burt, and Mr. Henry Morley. The extensions of the hospital thus opened could not have been undertaken were it not for the munificence of King Edward VIII.'s Hospital Fund, and the Worshipful Company of Drapers.

Royal College of Physicians of Ireland.

DR. JOSEPH REDMOND, President of The Royal College of Physicians, entertained a large party at dinner in the College Hall on May 8th. Dr. Redmond presided. On his right were his Excellency the Lord Lieutenant the Very Rev. Father Delany, S.J.; the Master of the Rolls, the Provost of Trinity College, Sir Francis Cruise. Mr. Justice Dodd, the President R.A.M., Sir A. Vicars, K.C.V.O.; the Registrar-General, and Serjeant O'Connor. On his left were Mr. Swanzy, President Royal College of Surgeons; Lord Anson, A.D.C.; Dr. Atthill, Mr. Justice Boyd, Dr. Little, the Hon. the Recorder of Dublin, the Dean of the Chapel Royal, Sir P. Coll, K.C.B.; Lieut.-Colonel Scott Elliott, Sir Charles Cameron, C.B., and Sir John Moore. The Lord Lieutenant, who was warmly applauded, replied. He said there were some notable names connected with the career of the College, such as Graves, Stokes, and Corrigan; and when they spoke of distinguished men they could not but think of one happily, still amongst them, though not able to be present there that night—their Senior Fellow, Sir John Banks (applause). It was enough to pass his house in Merrion Square to have one's mind raised to feelings of thankfulness because of the fact that such a noble personage was still amongst them, an example of what could be done by true attention to duty and true goodness and kindness of heart (applause). The College was the third body in the United Kingdom to institute diplomas in public health, Trinity College, being the first. The College of Physicians was the first medical body to admit women to its licences (applause). At present there was a kind of awakening in the public mind as to the importance of having these matters dealt with more fully and efficiently than heretofore (hear, hear). That College could do much not only to awaken but to guide any great movement. Among the influences which they might look for from that institution was that of increasing a tendency of which, perhaps, they saw too little in Ireland, namely—the habit of not allowing differences in political and other matters to interfere with social progress. He endorsed what the President had said about the earnestness and zeal of his distinguished predecessor, Lord Dudley, who had shown the permanency of his interest in Irish matters by the manner in which he had presided over the Congested Districts Commission (applause). The President proposed the toast of "The Guests." They were all guests, and he had the melancholy privilege of drinking their healths alone (applause). The Lord Lieutenant proposed the toast of "The President," which was enthusiastically honoured.

Meath Hospital and County Dublin Infirmary.

LAST week the new Home for Nurses, which has recently been added to the Meath Hospital and County Dublin Infirmary, was opened by His Excellency the Lord Lieutenant. There was a large company present. Sir John Moore presided. Mr. Francis Penrose, Secretary, read an address to His Excellency, in which a brief history of the hospital was given. Regarding the nursing arrangements in the hospital the address stated that in 1904, the committees having decided to take the nursing of the hospital into their own control, the duty immediately devolved upon them of securing probationers, and providing a residence for them. To meet the emergency of the housing accommodation a temporary arrangement was arrived at, by which several small wards in the hospital were set apart for the purpose; but the Joint Committee were confronted with the necessity of establishing permanent accommodation for the nurses, either by building a Home on the grounds of the Hospital or by renting houses in the vicinity. After mature consideration the Committee at length resolved to erect a Home on the grounds of the Institution, and trust to the charitable public to supply them with the necessary financial assistance. The Joint Committee were largely influenced in coming to this decision by the fact that the sleeping accommodation for the servants of the Hospital had become quite inadequate. The building contains accommodation for thirty nurses and fourteen servants, and is provided with everything necessary for their comfort. The sum of £5,306 15s. has been paid on account, leaving a balance due of about £600. A sum of over £250, and many useful articles have been contributed, including a piano, kindly presented by Mr. Charles Lawler, a member of this Committee, towards the furnishing of the Home. His Excellency then declared the Home open.

Post-Graduate Courses in Dublin.

THE President and Council of the Royal College of Surgeons have arranged to hold two courses of post-graduate study during the months of June and September respectively. The object of these courses is to render available the whole of the clinical material in the city for the post-graduate student, so that he may see as much as possible during the brief time at his disposal. Ten general hospitals are available, as well as the various hospitals devoted to special subjects. In the event of the post-graduate students exceeding a certain number at either of the courses, arrangements will be made to divide up the classes into practical working groups. The first course will begin on Monday, June 10th, 1907, and will terminate on July 2nd. The second course will begin on Monday, September 23rd, 1907, and will terminate on October 15th. Further particulars appear in our advertisement columns.

The Ingleby Lectures.

DR. THOMAS WILSON delivered the first of these lectures at Birmingham University on May 9th. Dr. Wilson said it was customary for the Ingleby lecturer to select some subject with which he had special or particular acquaintance, and he was following the usual custom that day. The lectures, he pointed out, were established in connection with Queen's College in 1876, and were intended to promote the advancement of obstetric surgery and medicine, being a branch of medical science in which Dr. Ingleby acquired considerable reputation. Dr. Ingleby practised from the year 1816 until his death in January, 1845, and he completed his fiftieth year shortly before his death. He was a victim to study and devotion to the duties of an immense practice. He was the first to practise obstetric surgery in Birmingham, and was one of the original members of the still flourishing Medical Benevolent Society, and as an evidence of the esteem in which he was held by his professional brethren he was elected president of the society in the year 1836. As an author in obstetric subjects he was without a professional rival, and his writings were evidently the outcome of close personal observation and sound judgment. Dr. Wilson then proceeded with his lecture. The next lecture will be delivered on Thursday, in the Medical Theatre of the University, at four o'clock in the afternoon.

The Judgment of Pharaoh.

SHOULD any of our readers feel interested in the work of a medical man in the direction of dramatic art, let them "hie to La Scala Theatre," in Fitzroy Square, where they will see represented one of the most gorgeous and artistic productions of stage-craft of recent years. And this, be it said, by a medical confrère, Mr. E. Distin Maddick, F.R.C.S., formerly a surgeon in the Royal Navy, surgeon to the Royal Italian Hospital, and subsequently in consulting practice in the West End of London. This position and these appointments were recently put on one side in order that the subject of their embodiment might devote his undoubted talents to the development of dramatic art. The result is seen in the erection of the most sumptuous and at the same time the most hygienic theatre in London, and the production of a play thereat, which, like the building, is something quite different from anything hitherto presented on the stage. The scenes are laid in the ancient Hebraic-Egyptian days, and during the progress of the play real camels traverse the desert, and apparently real lions (although they are huge dogs cleverly disguised as lions, as the Lord Chamberlain refused to license lions, and, we think, wisely) bound hither and thither in quest of prey, and the Oriental and barbaric splendour of the Court of Egypt is reproduced, as presumptive evidence of the work of a cultured and travelled scholar. The acting, like the house and the play, is of a refined order, and it affords us much pleasure to congratulate our confrère on an unquestionable success in his new departure.

The Irish International Exhibition.

THE Irish International Exhibition which was opened with full State by His Excellency the Earl of Aberdeen, Lord Lieutenant of Ireland, on the 4th inst., promises to be one of the most successful exhibitions of recent years. The grounds, which are situated in the neighbourhood of the well-known grounds of the Royal Dublin Society, are extensive and contain numerous fine buildings. As is only natural, the exhibition is not yet in full swing, but it is sufficiently advanced to enable its visitors to see that when everything has been completed it will be a most successful undertaking. Even at the present stage, it has been visited by large numbers. Amongst the most notable sections it may be mentioned the Fine Art section, which is universally stated to contain the finest selection of modern pictures which have ever been exhibited in Ireland, the Machinery Hall and the Canadian Pavilion. Many of the exhibits are of great interest to medical men, and we are sure that during the coming months they will find that a visit to it will well repay the cost, even if they have to travel a long way to see it.

A Medical Golf Club for Dublin.

AT a meeting held on May 6th, at 6, Merrion Square, to which a member of the staff of each of the Dublin Clinical Hospitals had been invited, the following resolutions were passed:—It has been decided to form a Society to be called the Dublin Hospitals Golfing Society, the membership is to be limited to the staff and assistant staff of the Recognised Clinical Hospitals, and in this category the Dental Hospital is included. Officers of the R.A.M.C. serving in Dublin will also be eligible for membership. The annual subscription has been fixed at 5s. Gentleman who are eligible and who desire to join are requested to send their names to the Honorary secretary, Mr. J. B. Story, 6 Merrion Square, and, if possible, to attend a meeting to be held on Wednesday, May 15, at 5 o'clock in No. 35, Dawson Street to elect officers and transact other business.

A Preposterous Counter-Claim.

At the Greenwich County Court recently, before Judge Willis, K.C., Dr. Middlebrook, of Eltham, recently sued David T. McCulloch for £3 12s. 6d., fee for medical attendance, and defendant counter-claimed for £50 damages for careless treatment and faulty diagnosis of his wife's illness, alleging that his wife met her death from this cause.—Mr. Mathew. (instructed by the solicitors of the London and Counties Medical Protection Society, appeared for the plaintiff). The doctor's claim being admitted, judgment was given for £3 12s. 6d., and His Honour then proceeded to the counter-claim.—The defendant, David McCulloch, said that he called in Dr. Middlebrook to attend his wife in November, 1904. Plaintiff told him that his wife was suffering from overwork and had gall stones and a growth. Plaintiff never mentioned that witness's wife was suffering from Bright's disease. Witness called in Dr. Rice, who at once pronounced the deceased to be suffering from Bright's disease. On January 7th he called on Dr. Middlebrook and asked him for his bill. He did not then complain, nor had he subsequently complained with regard to his treatment.—Dr. John Rice said he first saw the deceased on January 9th. She was in bed, and subsequently he was able to inform the husband that his wife was suffering from chronic Bright's disease.—Cross-examined: He had no knowledge of the treatment employed, and had never passed any opinion on it.—Dr. Middlebrook said that he diagnosed the deceased's complaint as Bright's disease on his first visit, and, in support of that statement produced his notes on the case. He never treated the case for anything but Bright's disease. His Honour, in giving a judgment in favour of Dr. Middlebrook, said the defendant's claim should never have been brought. Nothing that Dr. Rice had said had in any way supported the accusation brought against Dr. Middlebrook. The latter's treatment had been skilful and proper, and there was not the slightest evidence to show that any one of the defendant's statements was justified.

Royal Institute of Public Health.

The Harben Lectures this year will be delivered by Professor Dr. Paul Ehrlich, on June 5th, 7th, and 11th, at 5 p.m., subject, "Experimental Researches on Specific Therapeutics." Among special lectures arranged for will be one by Professor R. T. Hewlett, M.D., F.R.C.P., on Thursday, May 30th, subject, "The Problem of the Pure Milk Supply." On Thursday, June 6th, Professor G. Sims Woodhead, M.D., F.R.S., will lecture on "Blood Immunity." Dr. E. W. Goodhall, M.D., B.S., will lecture on "The Treatment of Infectious Diseases Regarded from the point of View of Hospital Administration," on Thursday, June 13th; and Dr. Louis W. Sambon, will close the Summer Course with a lecture on June 20th, on "The Development of Africa: A problem of Comparative Pathology." All these lectures will be delivered in the Lecture Theatre of the Institute, 37, Russell Square, at 5 p.m., and the attendance of all interested is cordially invited.

Medical Congress at Budapest.

We understand that the fifteenth International Medical Congress, held in Lisbon, have chosen Budapest the capital and residence of Hungary, for the site of their next assembly, and the preliminaries are already in process. His Imperial Majesty the King of Hungary has graciously extended it his patronage, and the State and town have each contributed 100,000 crowns to defray the expenses. There are to be 21 sections, each branch of science having a separate section assigned to it. August 29th, 1909, has been fixed as the date of opening, and the session will be continued till September 4th.

Schools of Medicine and North Dublin Guardians.

On May 8th at a meeting of the Guardians of the North Dublin Union, a question of great importance to the Medical Schools of Dublin came on for consideration. Mr. John Carolan, J.P., T.C., presided.

Mr. Long said he wished to have rescinded a resolution, which was passed on April 17th, and for that purpose he would move the following resolution: That, inasmuch as the resolution of the Board of April 17th, dealing with the sending of bodies to the School of Medicine would be a grave injury, not alone to the schools, but to the City of Dublin, that the portion of the resolution directing notices to be posted in the wards be rescinded; that certificates as usual be issued by the medical officers in attendance on the deceased, as required by Act of Parliament; and that the Master be directed to have all the legal formalities strictly carried out. Mr. Long said he was not concerned so much about the hospitals or about the officers there, as he was about the young men who were studying for the profession of medicine and surgery. Young men were already sufficiently handicapped in this country, and their opportunities were few, and he would not like to see them deprived of those which they had.

Mr. Denis Lynch moved as an amendment:—That the whole question be referred to a committee, which will consider it thoroughly, and after consultation suggest to the Board the best means of dealing with a question of such delicacy and importance; that officers and doctors be asked to attend, and all action be stayed pending the report. This amendment was then put, and adopted unanimously.

Aliens in the Port of London.

Dr. Herbert Williams, the medical officer of health for the Port of London, who has been responsible for the carrying out of medical inspection in the port under the Aliens Act since it came into operation, states that the work was conducted last year between the hours of 6 a.m. and 8 p.m. A certain proportion of alien steerage passengers were found to be "undesirable" on medical grounds and were refused admission. In nearly every instance they appealed to the Immigration Board, and, on appeal, a certain number of them were allowed to land. Last year 72,824 aliens arrived in the Port of London, of whom 29,003 were cabin passengers, 11,661 exempted second-class passengers, 17,221 transmigrants, and 14,939 of other descriptions. In the whole of the United Kingdom the aliens arriving numbered 465,000. The number of expansion orders made under the Act was 294. During the year 1,975 non-immigrant alien ships arrived in the port with 29,290 passengers and 550 immigrant ships with 43,534 passengers. Transmigrants were all examined with a view to the detection of any case of infectious disorder amongst them, while the immigrants were subjected to a more careful and thorough examination. In other ports there arrived 6,996 non-alien immigrant ships with 88,330 passengers and 3,561 immigrant ships with 294,340 passengers.

The Middlesex Hospital.

A festival dinner in aid of the funds of this institution was given on Friday evening at the Princes' Restaurant, when the Duke of Connaught occupied the chair. He was supported by Prince Francis of Teck (vice-president), the Duke of Northumberland (president), Lord Sandhurst, Lord Michelham, Lord Cheylesmore (chairman of the board), Lord Derby Lord Lathom, Sir Elliott Lees, Lord Duncannon, Mr. Andrew Clark, F.R.C.S., the Hon. Walter Rothschild, M.P. (treasurer), Colonel the Hon. C. G., Gathorne-Hardy, Mr. W. E. Gillett, Sir W. Vaughan Morgan, Sir T. H. Brooke-Hitching, Mr. W. H. Burroughes, Dr. J. Kingston Fowler, Mr. G. J. Marjoribanks, Sir R. D. Powell, Dr. William Duncan, Lord Rosmead, Mr. H. E. Ormerod, K.C., Sir. E. Hay Currie, Mr. S. Vaughan Morgan, Sir G. Anderson Critchett, Major General Sir Reginald Thynne, Dr. F. Ford Anderson Dr. W. E. Wynter, Mr. John Murray, Mr. C. H. Burnand, Sir William H. Humphrey, Colonel Charles Needham, Mr. Frank Debenham, Mr. W. C. Houghton, and Mr. F. Clare Melhado (secretary superintendent).

After dinner the Chairman gave the toast of "The King, the Patron of the Hospital," which was enthusiastically received.

His Royal Highness next submitted the toast of he evening, "Continued Prosperity to the Middlesex Hospital," with an eloquent appeal for funds. A list of subscriptions to the amount of £4,500 was announced during the evening.

Chemists' Exhibition.

At the Royal Horticultural Hall last week a very successful exhibition of articles of interest to pharmaceutical chemists was held by the *British and Colonial Druggist*. The exhibition naturally differed in many respects from that held for medical practitioners under the same auspices last summer, but there was still much of interest to medical men. One novelty that deserves mention was a substance known as "Ratin,"—a bacteriological preparation which is said to infect rats and mice with a disease from which they quickly die, but which is innocuous to man and all domestic animals. The preparation has been largely used in Germany and Denmark, and is now being experimented with in India. The various stalls were well loaded with things new and old, and the usual accessories in the way of music and refreshments were liberally attended to. The enterprise of the organisers was particularly shown in the fact that they paid the cab-fare of every chemist in the London radius who came to the Exhibition. Very large numbers of pharmacists from all parts attended.

International Red Cross Conference.

The following official delegates to the International Red Cross Conference, to be held in London in June, have been appointed:—

By the Admiralty.—Inspector-General Herbert M Ellis, K.H.P., Director-General of the Medical Department of the Navy; and Deputy-Inspector-General Arthur W. May, of the Medical Department of the Navy.

By the War Office.—Surgeon-General Sir A. Keogh, K.C.B., M.D., Director-General, Army Medical Service; Lieut.-Col. M. W. Russell, R.A.M.C., Deputy-Assistant Director-General, A.M.S.; Lieut.-Col. W. G. Macpherson, C.M.G., M.B., R.A.M.C., Deputy-Assistant Director-General, A.M.S.; and Lieut.-Col. J. E. Edmonds, R.E., of the Department of the Chief of the General Staff.

PASS LISTS.

Royal College of Surgeons of England.

At a meeting of the Council, on Thursday, May 9th, the following candidates, having passed the required examinations and conformed to the bye-laws, were admitted Members of the College:—G. H. Adam, F. O. Arnold, B.A., H. T. Ashby, B.A., P. H. Bahr, B.A., Camb.,H. J. Beddow, B.A., Camb., R. C. P. Berryman, John Birch, R. E. Brayne, Josiah Browne, C. W. G. Bryan, M. B. S. Button, H. V. B. Byatt, B.A., Camb., W. J. Chapman, P. J. Chissell, Spencer Churchill, B.A., Camb., E. B. Clayton, B.A., Camb., H. C. Colyer, P. S. Connellan, P. A. Creux, T. H. Davies, A. H. T. Davis, H. E. T. Dawes, B.A., Camb., Geo. Denholm, A. T. Densham, B.A., Camb., Horace Dimock, B.A., M. M. Earle, H. R. Elliott, C. A. Ellis, W. A. Fairclough, J. H. Farbstein, Marmaduke Fawkes, Norman Fowler, B.A., W. E. L. Fowler, C. H. S. Frankau, W. D. Frew, P. C. Garrett, Harold Gibson, W. S. Gibson, B.A., A. S. Graham, George Graham, R.A., W. R. Greening, F. W. W. Griffin, B.A., R. E. V. Hale, B.A., H. McC. Hanschell, R. N. Hartley, L. C. Hayes, A. W. Hayward, B.A., C. E. K. Herapath, G. A. F. Hayworth, B.A., W. de M. Hill, Hendrik Houwink, R. de S. Illesinghe, C. G. Jarvis, R. S. Jenkins, B.A., W. G. Jones, A. J. Kendrew, Solomon Krestin, Malcolm Leckie, H. E. Leeson, W. S. Leicester, B.A., Camb., R. L. Ley, B.A., Camb., Conrad Loddiges, Wm. Lovell, F. B. Lowe, J. B. Macalpine, C. F. F. McDowall, E. L. Marchant, W. B. Martin, J. H. Mayston, B. B. Metcalfe, H. L. Morgan, E. L. R. Norton, H. S. Ollerhead, Arthur O'Neill, G. L. Parsons, B. T. Parsons-Smith, Walter Patey, Stanley Paulin, C. A. Pemberton, E. C. Pope, O. C. W. Prausnitz, Geoffrey Price, J. L. Rankine, J. A. Renshaw, Kenneth Robinson, C. F. Rumsey, A L. Sachs, M.A.., Cambs., L. St. V. Welch, John Selfe, E. A. Shirvell, A. L. Singer, B.A., Camb., W. F. Skinner, F. G. Snoad, E. C. Sparrow, B.A., Camb., L. D. Stamp, Frank Standish, George Stone, A. A. Straton, J. R. Sutherland, R. E. Todd, S. S. Vazifdar, J. L. Walker, N. H. Walker, R. R. Walker, B.A.. Camb., H. G. Webb, Henry Weir, H. B. Wickham, J. W. J. Willcox, C. L. Williamson, L. A. Wilson.

Royal College of Surgeons in Ireland.

At a meeting of the President, Vice-President, and Council, held on Tuesday, May 7th, the following Examiners were elected for the ensuing year:—

FOR CONJOINT LICENCE, DIPLOMA IN PUBLIC HEALTH, AND PRELIMINARY.

Anatomy.—Alexander Fraser, F.R.C.S.; Bertram C. A. Windle, B.S., Univ. Dub.

Surgery.—Charles A. K. Ball, F.R.C.S.; Alexander Blaney, F.R.C.S.; F. Conway Dwyer, F.R.C.S.; G. Jameson Johnston, F.R.C.S.

Physiology and Histology.—Denis J. Coffey, B.S., R.U.I.; E. L'Estrange Ledwich, L.R.C.S.

Pathology and Bacteriology.—Arthur Hamilton White, L.R.C.S.

Midwifery and Gynæcology.—Frederick W. Kidd, L.R.C.S.

Biology.—John J. Burgess, F.R.C.S.

Ophthalmology.—Arthur H. Benson, F.R.C.S.; Patrick H. Maxwell, F.R.C.S.

Sanitary Law and Vital Statistics.—Edward Francis Stephenson, F.R.C.S., D.P.H.

Engineering and Architecture.—Caleb J. Powell, F.R.C.S., D.P.H.

Languages.—L. J. Woodroffe, M.A., Dub. Univ.

Mathematics, Physics, Dictation, and English Essay.—J. W. Tristram, M.A., Dub. Univ.

Dutch.—John C. Pretorius, B.A., Dub. Univ.

FOR FELLOWSHIP, LICENCE IN SURGERY (FOR REGISTERED PRACTITIONERS), LICENCE IN MIDWIFERY (FOR REGISTERED PRACTITIONERS), AND LICENCE IN DENTAL SURGERY.

Anatomy.—Patrick Joseph Fagan, F.R.C.S.; Alexander Fraser, F.R.C.S.

Surgery.—Alexander Blaney, F.R.C.S.; F. Conway-Dwyer, F.R.C.S.; G. Jameson Johnston, F.R.C.S.; Richard Lane-Joynt, F.R.C.S.

Physiology and Histology.—Denis J. Coffey, B.S., R.U.I.; E. L'Estrange Ledwich, L.R.C.S.

Pathology and Bacteriology.—Arthur E. Moore, B.S., Royal Univ.; Arthur Hamilton White, L.R.C.S.

Midwifery and Gynæcology.—Frederick W. Kidd, L.R.C.S.

Chemistry and Physics.—Edwin Lapper, F.R.C.P.; Robert J. Montgomery, F.R.C.S.

Dental Surgery and Pathology.—George M. P. Murray, F.R.C.S.; William G. Story, L.D.S.

Mechanical Dentistry.—Daniel L. Rogers, L.D.S.; Thomas F. Studley, L.D.S.

The Scotch Diploma in Public Health.

At the May meetings of the Examiners in Public Health of the Royal Colleges of Physicians and Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow, held in Glasgow, the following candidates passed the respective examinations: First examination—James Dundas, M.B., Edin.; Herbert James Norman, M.B., Edin.; Albert Davies Edwards, M.B., Lond. Second examination and admitted Diplomates in Public Health—James Dundas, M.B., Edin.; Ferniehurst Halidon Borthwick, M.B., Edin.; Albert Davies Edwards, M.B., Lond.; and William Edward Home, Fleet Surgeon, R.N., M.D, Edin., M.R.C.P.E.

At the inquest on the thirteen-year-old son of a painter named Cornhill, living at Clayton Street, Caledonian Road, it was stated that he became suddenly ill on April 30th and died on May 5th. A *post-mortem* showed that death was due to acute cerebrospinal meningitis, and the jury returned a verdict to that effect.

NOTICES TO CORRESPONDENTS, &c.

☞ **CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions, the same rule applies as to office; these should be addressed to the Publisher.

THE LAST OF THE LIGHT BRIGADE.

Surgeon-Major Lancelot Armstrong, who died at Weston-super-Mare, on Saturday last, is associated with the ride of the Six Hundred at Balaclava. He commenced the ride, but dismounted when men were falling, and attended to the wounded under the murderous fire of the Russian batteries. He was the only medical survivor, and almost the last of the celebrated six hundred.

DR. F. A.—We cannot inform you of any work on the subject of the effect of methylene blue in cancer in this country, but an interesting article on the question appeared in the Journal of the American Medical Association last November. The drug has been used for years by Dr. Jacobs, the writer of the article, and though he does not claim that it cures, in his opinion it gives relief and prolongs life. One case, cancer of the liver, has been treated for eight years, and the patient is not only alive but able to deal with the ordinary affairs of life.

ORIGIN OF "COLONEL BOGEY."

MEDICAL golfers will be interested to learn that the origin of the renowned Colonel Bogey is closely connected with one of their number. The "World of Golf" says he originated at Coventry in December, 1890, and that some six months later some of the club went to Great Yarmouth, where the idea was explained to Dr. Thomas Browne, R.N., the hon. secretary, who went out to play against Major Charles A. Wellman on this system.

At that time the "Bogey Man" song was in great vogue, a song with the refrain, "He'll catch you if he can!" and it flashed across the mind of Major Wellman when he was getting caught by bogey. "Why," said he, "this player of yours is a regular Bogey man."

A little while afterwards Dr. Browne was playing at the course of the United Service Club, at Alverstoke, in Hampshire, and introduced them to the "Bogey man," and after working out a score for him for that course they went out to play with him.

"Stay!" said the secretary at the moment of starting. "Every member of this club has a proper service rank. Our new member ought to be a commanding officer. He must be a Colonel!"

POST CARD.—The correspondent who questions the accuracy of our note, p. 471, May 1st, as to the attendance of Dr. Glendening on the Queen of Spain may, we think, rest assured that the gentleman in question has not returned to England. Many reports and contradictions have been bandied to and fro upon the whole affair, oftentimes with a want of delicacy that does not altogether redound to the credit of modern journalism.

DR. FINSEN AND HIS DISCOVERY.

MR. JACOB RIIS, the American author, says: "I learned from Dr. Finsen's own lips the story of his great temptation—how, when he found what he sought, the power to combat the disease with the ravening name ('lupus,' a wolf)—he lay awake one whole night, debating with himself whether to turn it to account in private practice—Finsen was a poor man—or to give it and his life to the world. He chose poverty, and the world is the richer for his sacrifice." Of course, when he decided to make public his discovery, Dr. Finsen only acted in accordance with the noble traditions of his prefession, but the temptation was nevertheless strong.—*Daily News.*

Meetings of the Societies, Lectures, &c.

WEDNESDAY, MAY 15th.

ROYAL MICROSCOPICAL SOCIETY (20, Hanover Square, W.).—8 p.m.: Exhibition of Pond Life. Papers:—Prof. A. W. Porter and Mr. P. F. Everitt: Diffraction Rings due to a Circular Aperture.—Mr. E. M. Nelson: An Improved Vertical Illuminator.

SOCIETY OF ARTS (John Street, Adelphi, W.C.).—8 p.m.: Dr. H. W. G. Macleod: Trypanosomiasis or Sleeping Sickness.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Mr. M. Collier: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Mr. B. Harman: Injuries to the Superficies of the Eye.

NORTH-EAST LONDON POST-GRADUATES' COLLEGE (Prince of Wales' Hospital, Tottenham, N.).—Cliniques: 2.30 p.m.: Skin (Dr. Meachen), Eye Mr. Brooks), Medical Out-patient (Dr. Whipham).

THURSDAY, MAY 16th.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND (11 Chandos Street, Cavendish Street, Cavendish Square, W.).—3 p.m.: Papers:—Dr. W. F. Robertson and Dr. G. D. McRae: Futher Bacteriological and Experimental Investigations into the Pathology of General Paralysis.—Dr. H. Devine: A Case of Katatonia in a Congenital Deaf-Mute.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.; Mr. Hutchinson: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Mr. M. Yearsley: Syphilis in the Ear.

NORTH-EAST LONDON POST-GRADUATES' COLLEGE (Prince of Wales' Hospital, Tottenham, N.).—2.30 p.m.: Gynæcological Operations (Dr. Giles). Cliniques:—Medical Out-patient (Dr. Whiting), Surgical Out-patient (Mr. Carson). 3 p.m.: Medical In-patient (Dr. Chappel). 4.30 p.m.: Special Demonstration of Surgical Cases (Mr. W. Edmunds).

HOSPITAL FOR SICK CHILDREN (Great Ormond Street, W.C.).—4 p.m.: Lecture:—Mr. G. E. Waugh: Hip Disease in Children.

FRIDAY, MAY 17th.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN (11 Chandos Street, Cavendish Square, W.).—5 p.m.; Wightman Lecture:—Dr. F. Taylor: Pneumonia in Children.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W. C.).—4 p.m.: Mr. W. Stuart-Low: Clinique. (Ear).

NORTH-EAST LONDON POST-GRADUATES' COLLEGE (Prince of Wales' Hospital, Tottenham, N.).—9.30 a.m.: Clinique:— Surgical Out-patient (Mr. H. Evans). 2.30 p.m.: Surgical Operations (Mr. Edmunds). Cliniques:—Medical Out-patient Dr. Auld), Eye (Mr. Brooks). 3 p.m. Medical In-patient (Dr. Leslie).

Vacancies.

Cheltenham General Hospital.—House Physician. Salary £65. per annum, with board and lodging. Applications to W. H Head, Secretary. (See advt.).

Cheltenham General Hospital.—Surgeon-in-Charge of the Branch Dispensary. Salary £90 per annum, with board and lodging at the General Hospital. Applications to W. H. Head, Secretary. (See advt.).

Incorporated Orthopædic Hospital of Ireland. Surgeon. Applications to J. W. Berthisle, Capt., Secretary.

Kensington Board of Guardians.—Second Assistant Resident Medical Officer.—The Guardians of Kensington require the services of a Second Assistant Resident Medical Officer for the Workhouse and Infirmary at a salary of £100 per annum, with apartments, board, and washing. Applications to the Clerk to the Guardians, Marloes Road, Kensington.

Middlesex Hospital, W.—Medical Official and Registrar to the Cancer Department. Salary £100 per annum, with board and lodging. Applications to F. Clare Melhado, Secretary-Superintendent.

Royal Albert Edward Infirmary, Wigan.—Junior House Surgeon. Salary £100, with apartments, washing, and rations. Applications to Will. Taberner, General Superintendent and Secretary.

West Suffolk General Hospital, Bury St. Edmunds.—House Surgeon. Salary £100 per annum, with board and lodging. Applications to the Secretary.

Brentford Union.—Second Assistant Medical Superintendent, etc. Salary £125 per annum, with lunch and tea daily and dinner. Applications to William Stephens, Clerk to the Guardians, Union Offices, Isleworth, W.

Bailbrook House, Bath.—Assistant Medical Officer. Salary £140 per annum, with board, lodging, laundry, and attendance. Applications to Herbert Coates, 39 Broad Street, Bristol.

North Staffordshire Infirmary and Eye Hospital, Hartshill, Stoke-on-Trent.—House Physician. Salary £100 per annum, with furnished apartments, board, and washing. Applications to the Secretary and House Governor.

Oldham Union.—Resident Medical Officer. Salary £120 per annum, together with furnished residence, coal, gas, rations, washing, and attendance. Applications to Horace A. Quarmby, Clerk to the Guardians, Union Clerk's Office, Oldham.

Appointments.

FRENCH, J. GAY, M.B., B.S.Lond., M.R.C.S.Eng., L.R.C.P.Lond., Surgeon to the Ear and Throat Department, with Charge of Out-Patients, at the Great Northern Central Hospital.

GILBERT, WILLIAM, M.B., Ch.B.Glasg., Assistant House Surgeon at the Huddersfield Infirmary.

HERTZ, A. F., M.B., B.S.Oxon., Assistant Physician to Guy's Hospital.

JORDAN, ALFRED C., M.D., B.C.Cantab., Medical Radiographer to Guy's Hospital.

MURRAY, H. LEITH, M.D.Aberd., Joint Pathologist to the David Lewis Northern Hospital, Liverpool.

REITH, W. R., M.D., M.S.Aberd., Certifying Surgeon under the Factory and Workshop Act for the Erdington District of the county of Warwick.

SHAW, LAURISTON E., M.D.Lond., F.R.C.P.Lond., Physician to Guy's Hospital.

SYMES, J. O., M.D.Lond., D.P.H., L.R.C.P.Lond., Consulting Physician to the Cossham Memorial Hospital, Kingswood, Bristol.

TAYLOR, FREDERICK, M.D.Lond., F.R.C.P.Lond., Consulting Physician to Guy's Hospital.

Births.

COOPER.—On May 9th, at 19, Sutton Court Road, Chiswick, the wife of Bertram Cooper, M.R.C.S.,Eng., L.R.C.P.Lond., of a son.

PRICE.—On May 7th, at Castle Cary, the wife of David Price, M.B., of a son.

GRAHAM.—On May 1st, at Gwydir House, Cambridge, the wife of J C. W. Graham, M.A.(Cantab.), M.R.C.S.(Eng.), L.R.C.P.(Lond.), of a daughter.

Deaths.

HIGGINBOTHAM.—On May 8th, at Mentone, France, William Higginbotham, M.D., formerly of St. Petersburg, in his 94th year.

JALLAND.—On May 9th, at Rollestone House, Horncastle, Robert Jalland, M.R.C.S.Eng., L.R.C.P.Lond., aged 76 years.

WHITE.—On May 3rd, at 24, Nevern Square, London, Charles Vaughan White, M.R.C.S., L.R.C.P.Lond., son of the late F. S. White, Esq., of Southsea.

MACKENZIE.—On May 11th, at 72, Warwick Avenue, London, W. Emily Eliza, widow of John Ingleby Mackenzie, M.D. Cantab, aged 67.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXIV. WEDNESDAY, MAY 22, 1907. No. 21

NOTES AND COMMENTS.

Specialists' Fees.

AN unpleasant but important public duty was performed by Mr. C. H. Fagge last week in bringing a High Court action for fifty guineas against Mr. A. C. Roberts, a district auditor. Mr. Fagge had performed an operation on the defendant's child, thereby saving her life. His usual fee was one of a hundred guineas, but in consideration of the defendant's position, and on the family attendant's representation, he reduced it by one-half; yet when the time came to pay, Mr. Roberts offered twenty-five guineas, which he considered sufficient. In court it was stated that the defendant enjoyed a salary of over eight hundred a year, and as the operation appears to have been performed in the suburbs and to have been thoroughly successful, the charge cannot be considered disproportionate. No doubt it was one of some magnitude to the defendant, but if he wished to have a London hospital surgeon from the West End, it was necessary that he should be prepared for a considerable fee. There are always a number of excellent young surgeons available who are thoroughly capable of performing skilled operations, and unless surgeons of reputation, holding senior hospital posts maintain the level of their fees, it is very difficult for the juniors to get the less-well-paid work for which they naturally look in the early years of practice till their names are established. Physicians and surgeons of assured status do themselves little good in taking nominal fees from middle-class patients, and they certainly inflict a grave injury on their junior brethren.

"Iron Ox" Decision.

A HIGHLY-IMPORTANT decision was given by Mr. Justice Parker in the Chancery Division on May 10th. The case was one brought by the "Iron-Ox" Remedy Company against the Co-operative Wholesale Society Limited, of Manchester, for an injunction to restrain the defendants from passing off a medicine which the plaintiffs thought might be mistaken for their preparation, known by the name of "Iron-Ox." The defendants called the medicine they manufactured "Compound Iron Oxide Tablets," but there was no evidence that anyone had been deceived thereby. We have not the slightest sympathy with either of the parties to the suit, because we consider the patent medicine business in its aim and essence to be opposed to the public interest; but we are staggered at Mr. Justice Parker's decision to grant the injunction asked for, at least so far as the use of the word "Iron Oxide" is concerned. Iron oxide is an ordinary chemical name, denoting a salt of the metal which is used in medicine, and to forbid the use of such because a trading company have invested capital in the use of the word "Iron-Ox," is a dangerous and far-reaching procedure. It is no case of Tweedle-dum and Tweedle-dee, but of the right of persons to obtain for themselves the use of common chemical names, and if carried out logically, a trader has only to register the name "Cod-Ol," or "Zinc Ox," for a physician to be precluded from prescribing cod liver oil or oxide of zinc. We hope the matter will not be allowed to rest.

College of Surgeons and its Members.

IN answer to a question put by Sir William Collins in the House of Commons last week, Sir Henry Campbell-Bannerman detailed the stage which the contest between the members and Council of the Royal College of Surgeons of England has reached. It will be remembered by those interested that Sir William Collins a little while ago introduced a deputation of members of the College to the Prime Minister with a view to enlisting the support of the Government in the movement for reform of the College which has been so long on foot, and has made so little way. The Prime Minister promised to have the matter attended to, and now is able to announce that Lord Crewe, as Lord President of the Council, has referred the petition of the members to the Council of the College, received their reply, and subsequently seen a deputation of the members. The latter have furnished a reply to the reasons against reform put forward by the Council, and this has been forwarded to the latter with an intimation from Lord Crewe that he will be glad to receive a deputation from the Council if they wish to send one. It may be taken, therefore, that the trouble is in a fair way to being settled, and certainly the thanks of the members are due to the Prime Minister and Lord Crewe for their trouble in the matter. It is more than an anomaly for the control of the College to remain in the hands of a small minority who take advantage of the wording of a Charter granted many years ago, to exclude the whole mass of members from any share in the government of their institution.

"Ox-Runners and Pimply Gut."

One half of the world, it is truly said, does not know how the other half lives; it may be hoped that the half of the world in which one lives will never eat the things which form the comestibles of another half. The other day in Hackney a firm bearing a German name was summoned at the instance of the Hackney sanitary inspector for selling 150 sets of ox-runners (the intestines of the ox), which were said to be unfit for human consumption. The reason which, in the eyes of the health authorities, disqualified these articles was that they were afflicted with "pimply gut," apparently a condition of infection of the lymph-follicles of the intestine. "Ox-runners" were said to be in vogue as a covering for black-pudding, and a witness was called to prove that the skins were considered as an edible portion of that delicacy. In the defence it was argued that runners were used also for making tennis-racquets as well as black-puddings, and that there was no evidence that the particular parcel was designed for the food of man. The magistrate held that though the goods were liable for seizure he would give the defendants the benefit of the doubt, and he dismissed the summons. Black-pudding sounds little enough inviting, but if it is liable to be compounded with ox-runners afflicted with pimply gut, we fancy the strongest argument has been made out for the East-Enders to follow the simpler life, at any rate as regards their edible luxuries.

Semper Paratus.

The hygienic lessons of the Japanese war have been dilated upon times out of number, but it is not a little significant of the character of that nation that the precautions which excited so much occidental admiration, and which were crowned with such striking success, are not merely war precautions. The Japanese realise that what prevents disease in time of hostilities is equally capable of preventing disease in time of peace, and it was remarked by the troops at Gibraltar that the Japanese sailors who disembarked there the other day for an outing, all carried their own water-bottles containing sterilised water. No aspersion was intended for the sanitary resources of the Rock, but the Japanese officers realise that when a good thing in disease-prevention is found it is as well to stick to it under all circumstances. The Japanese hygienic religion is not an affair for Sunday only.

LEADING ARTICLES.

EDALJI COMMITTEE'S REPORT.

Now that the Edalji case has been finally decided, it may with pardonable pride be pointed out that The Medical Press and Circular was the first and for several years the only paper that pointed out the injustice of the conviction of that unhappy man. It will be in our readers' memory that in November, 1903, we got up a petition which was largely signed by leading medical men, asking the Home Secretary to revise the conviction, and that, though pressed several times, nothing beyond a formal acknowledgment could be obtained from him. The subject was kept alive in our columns till the expiration of the reduced sentence, and then, feeling that all we could do had been done, we allowed the matter to lapse. The subsequent steps taken by Sir A. Conan Doyle and the *Daily Telegraph* to obtain a free pardon from the present Home Secretary have now been successful, and we congratulate Mr. Gladstone on having acted with justice and discrimination. We must, of course, accept the opinion of the committee that Edalji, by his own folly, brought himself under suspicion, and that the police, acting on that suspicion, sought to bring the crime home to him. The theory is a new one, and without access to the information in the hands of Sir Arthur Wilson and his colleagues, we are not in a position to criticise it. The course taken by Mr. Gladstone—that of granting a free pardon but withholding any compensation—is, under the circumstances, the nearest approach to justice that can be attained after all the complications of what he has described as "this extraordinary case." But, without wishing to lay claim to undue perspicacity, we think we are entitled to point out to the Home Office and to the public that the administration of justice cannot be conducted in a civilised country merely by a staff of forensic experts, however much experienced and however able. We are willing to acknowledge that a sound lawyer is a better judge of what constitutes evidence—in the Edalji trial at the Quarter Sessions there was no such person on the Bench—than a physician, if the lawyer will grant that *pro tanto* the sound physician is a better judge of what constitutes crime, of motive, and of mental responsibility. A physician knows that criminals differ in type as much as lunatics do, and that to arrive at a decision as to the probability of a certain kind of crime having been committed by a certain person it is necessary to make a diagnosis of that person's mental predisposition and predilections. For an intelligent diagnosis of such a kind the same training is needed as that which enables a physician to decide whether a mental patient is suffering from (say) dementia prœcox, recurrent mania, or general paralysis. A lawyer is hidebound by evidence and facts, both of which are without doubt of the highest possible value; the medical man goes back further and judges of motive, that is of how the facts elicited by the lawyer are ætiologically related to the mental and physical constitution of the suspected person. So that we claim emphatically that the system of justice in this country is incomplete without a strong admixture of a medical element with the legal, and it is a ridiculous anachronism that provides the Home Office with no staff of physicians to aid the Minister responsible for the administration of justice with the means of linking up fact and probability. We are far from claiming that criminology is a complete science; but it is a budding science, and one in which medical men alone can become expert. Medical evidence in court is none too respectfully received in many cases, and medicine rightly claims a position, not of representation before a court, but of equality with the judiciary. We have only to point to the Edalji case as one in point. At the time of the trial it was apparent to us on medical grounds that Edalji was wrongly convicted, and we protested. It has taken the lawyers nearly four years of revising, discussion, and study to arrive at the same conclusion. A little medical knowledge about the class of criminal who indulges in crimes of lust and violence, and of their type of mental constitution, would certainly have saved Edalji, in spite of his foolish letter-writing, from three years' penal servitude, and the whole country from another severe dislocation of faith in the integrity of justice in Great Britain. We clearly saw from the first the strongest *prima facie* case against Edalji's guilt, and it was reserved for a medical man, Sir A. Conan Doyle, finally to move the Home Office. There can be little doubt that there are many prisoners at the present moment suffering similar injustices, which a little of the sweet reasonableness of medicine would have averted. Surely in the Edalji case medicine has been justified of her children.

THE DISAPPEARANCE OF SMALL-POX.

THE vindication of a scientific theory can be brought about only by the test of practical experience. In many instances it is impossible, owing to the lack of knowledge of essential facts, to formulate anything more authoritative than a sound working theory. The science of medicine has at the present time to deal empirically with a vast number of problems presented to her consideration in the phenomena of disease. Fortunately it is often possible to deal with morbid conditions in a perfectly satisfactory way by the application of general principles deduced from accumulated experience of the past. The disappearance of plague and cholera from the United Kingdom and the gradual lessening of other specific infectious diseases were accomplished for the most part prior to the discovery of the *rôle* played by pathogenic bacteria in their pathology, and to the identification of the specific micro-organisms concerned. Even at the present day it is a commonplace of medical interest to remark that the organism of so well-marked a malady as small-pox has not yet been identified. The battle of the sanitarian against that loathsome malady, however, has been fought and won wherever the counsel of the orthodox and authoritative medical world has been followed with zeal and thoroughness. The result in London has been a whole year—that of 1906—without a single death from small-pox, while in the three preceding years the deaths from that cause had fallen to the small proportion involved in the figures, 13, 25, and 10. Had the main mass of the population of the metropolis not been protected by vaccination, and a large proportion of her unprotected citizens weeded out by death or rendered immune by attacks of the disease in the epidemics of recent years, the result of the invasion in 1903, 1904, and 1905, would probably have been multiplied a thousandfold. The negative order of the picture, however, is rarely taken into account by the anti-vaccinationist who shuts his eyes resolutely to the argument based on what might have been the state of affairs had not Jenner noted the protection afforded to dairy-workers by cow-pox, with which he first vaccinated a boy in 1798. At that time inoculation was largely practised, inasmuch as that method of direct communication of the disease offered the best chance of securing a mild attack. The mortality from small-pox was very great, while a great amount of blindness resulted, and pitting of the face, oftentimes of great and disfiguring severity, was the rule rather than the exception. Compulsory vaccination has changed all that, at least that is the profound belief and conviction of the scientific medical world. This view is fiercely opposed by the anti-vaccinationists, who contend that the decrease in small-pox is due to improved sanitation with its special preventive measures of notification, isolation and disinfection. Clearly the argument on neither side is capable of exact proof or disproof. Perhaps one of the strongest arguments in favour of the efficiency of vaccination is the way in which the disease picks out the unvaccinated for attack, and the excessive mortality of small-pox among unprotected persons. Yet the greatest proof of all is surely the fact that a little over a hundred years after Jenner's first vaccination, London, instead of being riddled and decimated with small-pox had not a single case of death from the disease during a whole year, in spite of the enormous relative increase of population. Jenner himself could hardly have hoped for a more triumphant vindication of his theory. To have prophesied such a result in his day would have been, to the mind of the wise as well as of the foolish, to have given food for ridicule. Men have come and men have gone, small-pox has disappeared, but the anti-vaccinationist goes on for ever. Of late years he has received some encouragement at the hands of Government, in spite of the solemn and weighty warning of the medical profession, and although the conscientious objector clause was provided to give the honest, if ignorant, antagonist to vaccination a graceful way of retreat, even that has not satisfied the professional agitator. It can but be regarded as unfortunate that many magistrates did not realise sooner that arguing and pleading with anti-vaccinators was merely to waste time, and that such methods only keep alive a controversy which should have died from inanition in 1898. As it is, Mr. Burns is preparing to pass a bill to make the way of the anti-vaccinationist still easier by enabling him to make a simple statutory declaration of objection, and it can but be expected that the idle and careless will take wholesale advantage of it, alongside of the prejudiced and ignorant. The logical correlative of primary vaccination is re-vaccination at school-age, but that ideal in the present state of public opinion is likely to remain an ideal for many a year.

CURRENT TOPICS.

The Health of Dublin.

THE contempt shown by the Corporation of Dublin for the lives of the citizens was emphasised again last week, when the Corporation declined to take steps to have the provisions of the Municipal Milk Depots Bill, at present before Parliament, extended to Ireland. The effect of the Bill would have been that the health authorities would have obtained wider powers for the supervision of the milk supply of the city. We do not know that much would have been gained, as it is not lack of power but lack of energy that hampers the Dublin Health authorities. The powers of which they are already possessed are far from being exercised as fully as they might be. The carelessness of the Corporation, however, in regard to the Bill is typical of the indifference which prevails in Dublin on all matters affecting the health of the citizens. Among the causes of the high death-rate in that city infant mortality is one of the most important, in spite of the fact that there are few if any married women employed in industrial work. By their recent decision the Corporation declines to take any measures to safeguard the health of the infant population, to whom milk is so important an article of diet. The only satisfactory point in the whole business is that the scandal is so open that some of the daily papers have at length lifted their voices in protest.

National Sanatorium Association.

AN eminently successful banquet was given in the Grand Hall of the Hotel Cecil on May 14th, by the National Association for the establishment and maintenance of Sanatoria for workers suffering from Tuberculosis, of which the Princess Christian is President. The chair at the dinner was taken by the Prince of Wales, who was supported by Prince Christian, in the vice-chair, and a large number of ambassadors, noblemen, and gentlemen. After the usual loyal toasts, the Prince proposed the toast of the evening, namely, that wishing success to the Association. In an excellent speech he showed that he had a very clear idea as to the aim of the Association and a good knowledge of its needs. The object is to help the working-classes to help themselves in the matter of providing sanatoria and maintaining them, and what is not less important, to give to the convalescent patients by means of a farm such employment as not only will be useful to their fellows, but will fit them to return to their own work when health is established. The Association numbers among its supporters a large number of friendly societies and trade unions, all of which are prepared to contribute liberally to the upkeep of the sanatoria as they are built. The first has already been opened at Benenden in Kent, but the number of beds available for workers is utterly disproportionate to the need for them. The movement is deserving of the warmest support because it is being managed on sound businesslike lines, and money is not being sunk in palatial buildings and extravagant fittings. Moreover, by the ability of the Association to take charge of a consumptive bread-winner on the recommendation of his society, the sick-pay he is entitled to can go wholly to his dependents. At present the provision of sanatoria for the working-class is in a pitiable condition, for throughout the country, in which some 70,000 persons a year die of tuberculosis, only something like 1,000 beds, all told, are capable of being used. It is gratifying to be able to record the success of the Prince's appeal, for no less than £13,261 was subscribed at the dinner, including 100 guineas from the Chairman himself.

Coroners and Death Certificates.

THE granting of death certificates is one of the most important and responsible duties that devolve upon the coroner. Indeed the document in question may be regarded as the outward and visible token of the semi-judicial function which he is called upon to exercise. The recognition of the vital importance of the death certificate lies at the root of the strong conviction held by the majority of medical men that coroners should always be chosen from members of their own profession. Last week a Medical Officer of Health reported in a scathing manner upon the loose way in which certificates of death had been in some cases granted by the district Coroner. He maintained that from a public health point of view the practice was dangerous. In several cases the cause of death had been reported as "probably convulsions," whereas there is no such disease as "convulsions," which are only a symptom of disease. In a case of death from spotted fever, in which the only apparent symptom was convulsions, and in which death ensued within twelve hours of the seizure, it was quite possible that if the parents had not obtained medical aid—as they frequently did not in cases of supposed convulsions—the death would have been certified as "probably from convulsions." In this contingency spotted fever might have spread to a serious extent. In the ensuing Council discussion a member said that quite recently the coroner had criticised the conduct of a Wrexham medical practitioner in refusing to give a death certificate, although the doctor had not seen the deceased before death ensued. Now it is certain that a medical man, even if he has not seen a patient during life, is in a far better position to give a certificate of death than a lay coroner, and if it is risky for a medical man to give such a certificate, as it undoubtedly is, *a fortiori* it is highly undesirable that a coroner should be in a position to do so.

The Cost of Small-Pox.

AT the last meeting of the Metropolitan Asylums Board, a long and interesting discussion took place on the provision of beds for small-pox patients in London. One of the speakers who raised the question of cost showed that to keep London in a state of preparedness for a possible outbreak of small-pox, the Board are spending on the hospitals and ambulance services £89,000 a year, and that for this enormous outlay they could only point to twenty-seven cases treated last year. The other speakers did not seriously dispute the figures, so that they may be taken as substantially correct. The matter after discussion was referred to the General Purposes Committee for investigation, but there can, one fears, be little hope that the Committee will be able to do much to reduce their expenditure. It does seem that the British is the most unpractical of nations, for it declines to insist on the [proper safeguards against small-pox, namely, vaccination and re-vaccination, and yet while it spends large sums annually on primary vaccination, at the same time it pays these stupendous sums for small-pox isolation. Every intelligent man knows that there is the choice of two methods for combatting the disease, either efficient vaccination with re-vaccination, or the provision of large isolation hospitals. In London at the present moment things have reached a climax, for money is being freely disbursed both for vaccination and small-pox treatment, and the amount reaches a respectable total. Perhaps some day the paradox of it will strike the observant ratepayer, but as it is he smiles and groans alternatively.

Hospital Abuse and the Lay Press.

One cannot wonder that the question of hospital abuse is attracting attention in the lay Press, and if some of the weekly papers of the baser sort have seized the opportunity to indulge in general abuse of the medical profession and hospital managers, the latter have, to some extent, themselves to blame. It is, of course, unfortunate that the man in the street cannot be rightly instructed in the question, since it is with him that the solution of this, as of most other practical problems, finally rests. The formation of public opinion can hardly be aided by such views as Mr. James Douglas publishes in a recent number of *M.A.P.* Mr. James Douglas is well known as a gentleman of melodramatic imagination, but this article of his is particularly fertile in exaggeration. "The hospital nurse is a white slave. . . . She is brutally overworked and underfed. . . . A few nurses are lucky enough to marry a doctor, but the majority of them find rest in an early grave." An accusation of polygamy is by no means the only charge he brings against medical men. "The central hypocrisy of the hospital is the glittering staff of honorary consultants." "In the East End of London the cheap doctors are a public nuisance and a public danger." "Hundreds of lives are lost through the gross incapacity of young doctors who are learning their trade at the expense of their patients." These are samples of the wit and wisdom with which Mr. James Douglas entertains the public. To him, as to some greater men, consistency is a matter of small importance. Thus we read that "the poor unanimously detest it" (the hospital), while at the same time "the hospital habit ~~is~~ common among the poor." We hope this sort of nonsense is not really typical of the attitude of any section of the public toward the hospital question, but apparently there is a public willing to pay for it.

PERSONAL.

Professor S. Ehrmann gave an address at the first meeting of the newly-formed Austrian Society for the Repression of Venereal Diseases.

Professor Wolfram C. Fuchs, of Chicago, has just died of malignant disease which is believed to have been caused by exposure to Röntgen rays.

Dr. Teizo Iwai, Physician to H.I.H. Prince Fushimi, has been appointed an Honorary Member of the Fourth Class of the Royal Victorian Order.

Dr. Doumer, of Lille, will read a paper on "The Fundamental Principles of Electrotherapy" at the British Electro-Therapeutic Society on Friday next.

Dr. William Hunter has been nominated Curator of the Museum of the Royal College of Physicians of London.

Dr. E. Cyril Doyne has been appointed honorary assistant surgeon and Dr. A. Douglas Hamilton assistant physician to Chester Infirmary.

Sir Thomas Frazer, F.R.S., Professor of Materia Medica in the University of Edinburgh, is to receive the honorary degree of D.Sc. at Cambridge University.

Sir William Collins is to preside at the annual general meeting of the Asylum Workers' Association at the Medical Society's Rooms, Chandos Street, W., on May 29th, at 4 p.m.

Colonel J. Lane Notter will take the chair at the provincial meeting of the Royal Sanitary Institute at Plymouth on May 31st. The subject for discussion is Infantile Mortality.

Dr. J. Walker Downie has been elected President, and Dr. R. Barclay Ness and Dr. Joshua Ferguson, Vice-Presidents, of the Glasgow Medico-Chirurgical Society for the next session.

Dr. James Evelyn Pilcher will deliver the address at the American Medical Editors Association at Atlantic City on June 1st. His subject will be "The Future of Medical Journalism."

Mr. R. H. Swanzy, President of the Royal College of Surgeons of Ireland, presided at the annual meeting of the King's Coronation National Fund for Nurses in Ireland on Monday, May 13th.

Dr. Alexander McPhedran, of Toronto, will preside at the fortieth annual meeting of the Canadian Medical Association at Montreal on September 11th and following days.

Dr. Donald MacAlister, M.D., LL.D., D.C.L., will take the chair at the dinner to be given by the Glasgow University Club, London, at the Trocadero Restaurant on May 31st, at 7.30 p.m.

Sir David Gill, LL.D., K.C.B., D.Sc., F.R.S., late Astronomer-Royal at the Cape of Good Hope, will preside at the British Association for the Advancement of Science annual meeting at Leicester on July 31st.

The late Lieut.-General George E. Baynes, of Hayward's Heath, has left by will £1,000 to Guy's Hospital and the Royal Hospital for Incurables, Putney, and the residue of his estate, after paying all bequests, to King Edward VII.'s Hospital Fund for London.

Dr. Knowsley Sibley will submit a resolution advocating a central hospital authority for London at a special general meeting of the Metropolitan Counties Branch of the British Medical Association, to be held on Thursday, June 6th, at St. James's Vestry Hall, Piccadilly, at 4.30 p.m.

Baron Takeo Ozawa and Dr. Nagao-Ariga have been chosen by the Japanese Red Cross Society, and Surgeon-Major Kasai, Colonel Gori Shibi, and Surgeon Kenji Kawanishi by the Japanese Government, as representatives at the forthcoming Conference of the Red Cross Societies.

Professor Paul Ehrlich, Director of the Royal Institute of Experimental Therapeutics at Frankfort, will deliver the Harben Lectures at the Royal Institute of Public Health on June 5th, 7th, and 11th. The subject he has chosen is "Certain Experimental Researches on Specific Therapeutics."

A Clinical Lecture

ON

THE TREATMENT OF PNEUMONIA. (a.)

By Sir JAMES BARR, M.D., L. and L.L.D., F.R.C.P., F.R.S.E.,

Senior Physician, Liverpool Royal Infirmary; Chairman of the Medical Faculty of Liverpool University; President of the Lancashire and Cheshire Branch, British Medical Association.

PART I.

Gentlemen,— We have just had three cases of pneumonia in my wards, male patients, æt. respectively 7, 17, and 40. There is nothing out of the common in these cases, but the subject is to me a very interesting one, and therefore I wish to make these cases an excuse for giving you a lecture on the treatment of this disease.

The boy, æt. 7, had a fairly sharp attack, involving the whole of the left lung. He was admitted on the third day of the disease, and the crisis happened on the ninth day. His temperature which was controlled by an ice-bag on the abdomen, ranged from 102° to 104° Fah., his pulse 140 to 160, and his respirations 40 to 60. His breathing had the character which you often notice in this disease in children, viz., it was catchy and at the end of the inspiration there was a distinct pause. This, as I have often pointed out, renders great assistance to the right side of the heart, which is very much needed by these small weak hearts. He had herpetic spots on the lips and tongue. He is now convalescent.

The youth æt. 17, was admitted April 25th, 1907, suffering from well-marked cardiac failure accompanied by urgent dyspnœa. He had rheumatic fever, several times during the last fourteen years, accompanied on more than one occasion by endocarditis and pericarditis. He has now a double aortic murmur, dilated and hypertrophied heart, mitral pre-systolic and systolic murmurs, and a dilated left auricle, adherent pericardium, and well-marked *pulsus paradoxus*. On May 2nd his temperature which had previously been subnormal, ran up to 100.8°, pulse 150, and respirations 36. When I saw him the following day his temperature was 103.2° Fah., pulse 160, and respirations 40. There were the usual signs of pneumonia of the left lower lobe. Dr. Baker had found pneumococci, streptococci, and staphylococci in his sputum. We did not examine his blood for lime salts, but there was no doubt in my mind that they were deficient as his expectoration was very hæmorrhagic, and he had slight epistaxis. He was therefore put on a mixture of calcium chloride and the tincture of the perchloride of iron. There was a large mustard poultice applied as a counter irritant to the left back, and he had an injection of 10 cc. of a polyvalent anti-streptococcal serum. The patient looked very ill, but I told my house Physician that in my experience valvular heart disease in young people did not much increase the gravity of the prognosis in a case of pneumonia. In these cases the heart muscle is healthy, and responds well to treatment, but it is quite a different matter when you have to deal with a fatty or fibroid heart. On the following day his temperature became normal, and in the evening rose to 100°, and on the 5th became subnormal, and has since continued so. This is a good example of what can be done if you get hold of a case early and treat it energetically. It also shows you that the pneumococci are not the only organisms which can give rise to pneumonia.

The man æt. 40 suffered from pneumonia of the right lower and middle lobes, with slight pleuritic effusion, in the right side. He is a very spare delicate man, had an attack of pneumonia nine years ago. This attack began on April 27th, and the crisis occurred on the night of May 3rd. His highest temperature in hospital was 103.2, pulse 120 and respirations 44. His teeth were septic, he had a slight herpetic eruption on the lower lip, and his expectoration was mucopurulent. The lime salts in his blood were only in the proportion of 1 in 8,700 parts of blood. He was therefore at once placed on a mixture of chloride of calcium and iron.

I do not claim any special credit for the success of these three cases, the treatment of which was of the general routine character which you see in my wards, and you often see much more severe cases all of which have not such a happy termination. I therefore wish to-day to take a much wider view of the treatment of this disease, which in my opinion is one of the most important diseases which you will have to encounter when you enter into private practice.

The widespread prevalence of pneumonia and its fearful mortality must always make the study of the treatment of this disease an interesting one for medical men. The utter futility of all treatment in many cases should I think make us approach the subject from the standpoint of prevention, a line of action which has hitherto scarcely commended itself to the medical profession. There is a frequent cry in the present day that the general practitioner is being crushed between the upper and nether millstones of special practice on the one hand, and the hospitals and cheap dispensaries on the other. If the general practitioner is to be restored to his former position as the friend and counsellor of his patients, he must teach them that the preservation of health is even more important than the cure of disease, and that his income should increase with the healthiness of the community and the fall in the death-rate. In this way the interests of Society and the practitioners of medicine will be linked together, and the necessity for even the existence of the surgeon and the specialist must be a gradually diminishing quantity.

From this standpoint let us review the disease in question, the incidence of which according to Jürgensen, equals on an average 3 per cent. of all diseases, while the death rate stands at 6·6 per cent of the total mortality. These statistics would show that the percentage mortality of

---

(a) Delivered at the Liverpool Royal Infirmary, May 7th, 1907.

pneumonia is more than twice as great as the average of all other diseases combined. In Liverpool, in 1905 the percentage death-rate of pneumonia to deaths from all causes was 9.7 whereas in 1896 it was only 7.6, and the deaths per 100,000 inhabitants in these two respective years were 187 and 172. The incidence and case mortality is rather increasing. The death-rate is usually put down at 15 to 25 per cent. If we reckon that one in six affected dies, then over 1 per cent. of the whole population of Liverpool is affected yearly. Why should anyone get this disease? It is an infective process for the most part due to the pneumococcus of Fränkel, though many other micro-organisms play an important *rôle* in its causation, such as the influenza bacillus, staphylococci, streptococci, and practically all the pathogenic bacteria. During the last sixteen years the prevalence of influenza has led to an increase of pneumonia. Here the inflammatory mischief is of a low congestive type and often rapidly fatal; but the bacillus of Pfeiffer does not seem to lead to the marked consolidation of the lung which takes place in cases associated with the pneumococcus of Fränkel. However, in these cases there is not infrequently a mixed infection. The pneumococcus usually exists as a harmless organism in the mouth and upper air passages. What, then, are the predisposing causes which give rise to its cultivated malignancy in the air cells giving rise to a disease which occurs in all climes? Its incidence is as great in some tropical countries as in northern latitudes. In this country it reaches its maximum about December and January, and is about twice as frequent in the winter and spring months as it is in the summer and autumn. It is less prevalent in the country than in the cities, and less among those who lead an outdoor life than among those whose occupations confine them to close apartments. It rarely arises at sea, and none of the polar expeditions seem to have suffered from it. Exposure to cold seems to lead to catarrhal affections rather than to true pneumonia; sudden variations of temperature may so depress the resisting powers as to become a markedly predisposing cause of the disease. It has been correctly asserted that exposure during sleep increases the predisposition to the disease, and this is no doubt due to the lessened resistance of the nervous system. This applies more especially to the aged and young, whose resisting powers are easily enfeebled. Consumptives and others who can keep the furnace burning within, readily withstand the cold air in their bedrooms, though cold draughts may readily induce catarrhal conditions. Frequent draughts of alcohol are, in my opinion, a much more important predisposing cause than any draught of cold air, and this may perhaps to some extent account for its somewhat greater prevalence among men than among women. While the incidence is less among women the mortality is greater perhaps owing to their having a smaller vital capacity. It frequently attacks those of strong constitution, but rarely when they are in good health, while the weak and debilitated are very prone to the disease. The way to prevent pneumonia is to increase the resisting power of the individual, hence you should encourage temperance or even total abstinence, and the avoidance of all debilitating agencies; have an abundant supply of fresh air night and day, maintain the body temperature by a proper supply of food and suitable external clothing, and warmth to assist the regulative mechanism of the body in maintaining and distributing the heat which it has generated. A fever patient may be packed in ice so long as the temperature is high, but if the treatment be continued after the temperature has fallen to normal you quickly get congestion and œdema of the lungs. When we see a big, plethoric, pot-bellied man, perhaps with a heart infiltrated with fat, and who gets out of breath on the slightest exertion, how often do we contemplate what poor chance such a one would have with an attack of pneumonia? It is the duty of the medical adviser of such an individual, to point out to him that he is living in a fool's paradise, and he must either never get pneumonia or be prepared for the struggle when it comes.

The mouth (including the teeth) and nares should be kept scrupulously clean; a foul-mouthed individual is liable to many troubles. As many of the micro-organisms which induce pneumonia are introduced by other paths than the respiratory passages all sources of pulmonary infection should be obviated. The prevention of pneumonia must alway rest with the medical adviser; the work of the medical officer of health can only be indirect by improving the general sanitary conditions of life, and in dealing with epidemics of the disease.

Your clientele will, however, get pneumonia, in spite of you, and we will now consider how we should deal with such a case when it does occur. Early recognition is of great importance. You must not keep hovering between conflicting opinions as to whether the patient has got pneumonia, or typhoid fever, or some other disease; waiting to see what will turn up. You must be prepared to treat the individual rather than the disease. You must find out the condition of every organ of his body. and if you do this the affection will not long escape your investigation.

A typical case with a flushed face, rapid breathing, high temperature, and a stabbing pain in the side is early recognised, but the majority of cases are not typical in their outset. In the young and aged errors most frequently occur, but with careful examination every case should be diagnosed within the first twelve or twenty-four hours. If you have any doubt in your mind as to what the case may turn out to be do not let your doubt interfere with your appreciation of the disturbances of the physiological processes of the various organs of the body. The febrile process and quickened respirations should arrest your attention.

This is a disease which varies very much in intensity and its prominent symptoms are more or less pronounced according as the individual is robust and plethoric, or weak and debilitated. But however the attack may arise the temperature affords a reasonable point of attack and I am strongly in favour of the increased dissipation of heat. It is therefore well to let the patient have a warm bath with plenty of soap, but if this be impracticable either from the condition of the patient or the environment he should be well washed, and the action of the skin encouraged by a diaphoretic mixture. If the temperature rapidly reaches a high level such as 104° Fah., the sooner a large ice-bag is applied to the abdomen the better Promptitude of action in the early stage often arrests the spread of the disease and may even arrest its further progress.

The question of blood-letting is one which perennially crops up, and I have no doubt in some few plethoric cases it does good. If it be deemed necessary in any particular case the sooner it is performed the better.

It should never be adopted after the first 48 hours, and never at any time if the pulse be small and feeble and compressible. Pneumonia in the female is often relieved by a commencing menstruation, and an epistaxis is occasionally beneficial. If at the beginning of the disease there be a full, bounding pulse and laboured respiration in a plethoric individual you may abstract 10 or 12 ounces from the arm. Venesection should not be performed on the very young, the old, or debilitated. After bleeding the patient should abstain from fluids for some hours. The cases, however, in which venesection is beneficial are few and far between.

VENTILATION.

The room should be the best in the house, and if possible should contain at least 1,000 cubic feet for each occupant, and the whole air of the room should be changed three times every hour. Often we find the patient, a nurse, and one or more friends in a small room of about 1,000 cubic feet, from which all fresh air is religiously excluded. How can a patient be expected to withstand such slow suffocation for a week? The physician may perhaps order 20 cubic feet of oxygen, which is equivalent to about 100 cubic feet of air, and may thus console himself that he is aerating the patient's blood. The air contains as much oxygen as the patient's blood can take up, and we have not merely to apply oxygen, but also to get rid of the carbonic acid which is best effected by an abundant supply of fresh air. Of what value are 20 to 60 feet of oxygen compared with 72,000 cubic feet of air, which supply the patient should have every 24 hours. I am pleased to think that the craze for cylinders of oxygen is dying out. There is no difficulty whatever in freely ventilating a room. Feverish patients do not catch cold, so that bugbear may be set on one side. Of course I would not recommend a draught of cold air to be played on the patient, lest it should set up a catarrhal condition or rheumatic pains. Night and day a stream of pure air should be admitted without creating draughts, I usually throw a window widely open. Dr. W. P. Northrup, a New York physician, has lately been treating pneumonia patients on the open roof of the hospital, for six hours a day in all weather, when harsh high winds, rain, and snow did not prevent.

The atmosphere of the room should be maintained about 60° to 65° Fah., by a large fire. The ordinary atmosphere at this temperature is not saturated with moisture and is therefore capable of holding the patient's exhalations, and there is not much danger of him drowning in his own excretions. I have never found the atmosphere in this climate so dry as to require any additional moisture. The man who invented the bronchitis kettle should have been hanged; death from strangulation would only have been a fair return for the number of deaths from drowning caused by his appliance

So long as a strong light or radiant heat from the fire is not playing on the patient, the more bright and cheerful the room the better. I do not believe in converting the bedroom into a dark chamber, which makes it difficult for the patient to distinguish day from night, and is apt to give him the impression that he is cast into outer-darkness. If the patient has a comfortable night he will not require much sleep during the day.

Whatever means be adopted for dealing with the temperature of the patient it should be kept within moderate bounds, as high temperature leads to granular degeneration of the heart muscle, sleeplessness, delirium, and nervous exhaustion. It is often sufficient to keep the patient very lightly clothed, and then allow free escape for the evaporation of the sweat which thus carries off a large amount of latent heat. All eiderdowns, cotton wool, waterproofs, and every impervious covering should be avoided. A large moist poultice, if the patient be lightly clothed and evaporation allowed to take place freely, removes a great amount of latent heat. The object should be to cool the patient, not to keep the poultice warm. However, I have almost abandoned poultices as they disturb the patient too much, and for the reduction of temperature I prefer the use of ice-bags to the abdomen. I usually apply a pure mustard poultice for half an hour as a revulsive agent at the begining of the disease.

(*Part II., conclusion, will appear in our next issue*).

Note.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by Sir James Barr, M.D., LL.D., F.R.C.P., F.R.S.E., Senior Physician Liverpool Royal Infirmary Chairman of the Medical Faculty of Liverpool University, President of the Lancashire and Cheshire Branch, British Medical Association. Subject: "The Treatment of Pneumonia," concluded.*

ORIGINAL PAPERS.

OBSERVATIONS ON THE OPERATIVE TREATMENT OF INFLAMMATORY DISEASES OF THE UTERINE APPENDAGES, BASED ON A CONSECUTIVE SERIES OF 120 CASES.

By ARTHUR E. GILES, M.D.,
B.Sc., Lond., F.R.C.S.Ed.,

Surgeon to the Chelsea Hospital for Women: Gynæcologist to the Prince of Wales' General Hospital, Tottenham.

In discussing the subject of the surgical treatment of inflammatory conditions of the ovaries and Fallopian tubes, it is, happily, not necessary to begin with a vindication of the justifiability of this treatment. This has been settled by medical public opinion, on the basis of the work of pioneers in this branch of surgery. I feel, however, that it is fitting that in making some observations which are the outcome of my personal experience, I should linger a moment on the threshold to pay a whole-hearted tribute to one of the most eminent of those pioneers, who gave me my first instructions in gynæcology as a student, and whose stimulating enthusiasm led to my taking up the special branch of medicine in which he was a master. I refer to my honoured teacher and friend, Dr. C. J. Cullingworth.

Some fifteen years ago Dr. Cullingworth read before a sister society an important communication on "The Value of Abdominal Section in Certain Cases of Pelvic Peritonitis, based on a personal experience of 50 Cases," with an appendix giving the results of a second series of 50 cases. It was a masterly contribution, involving an enormous amount of work, and gave rise to a heated discussion in which Dr. Cullingworth, like most pioneers, came in for a great deal of adverse, I might almost say, hostile, criticism. But the criticisms were not all adverse; three speakers entirely concurred in Dr. Cullingworth's views and it is interesting to note that these three—Mr. Mayo Robson, Dr. Heywood Smith, and Prof. J. W. Taylor—have since then been presidents of the Society. I think that there is no doubt that Dr. Cullingworth's teaching has been accepted by the great majority of the profession as well as by nearly all gynæcologists of the present day; and that the surgical principles which are adopted, for example, with regard to a diseased appendix are considered equally binding in dealing with diseased Fallopian tubes. Further, with the great reduction in operative mortality it has been conceded that women have a right to ask relief from conditions that rob them of health and usefulness as well as from those that directly threaten their life.

Many conditions of chronic non-suppurative disease of the tubes impair health; and many suppurative conditions imperil life; and I have made this distinction the primary basis of the classification of my cases. Being relieved by foregoing considerations from the necessity for pleading justification for surgical treatment, it is not necessary that I should present a detailed review of the cases; it will be sufficient if I present, as a text, a tabular statement of them, referring more fully to such as illustrate my observations in some special fashion.

The classification of the cases on the list is as follows:—

I.—Non-Suppurative Conditions.
1. Salpingitis.
(*a*) Unilateral disease 11
(*b*) Bilateral disease 16 (1)
———27 (1)
2. Hydrosalpinx and Tubo-ovarian cyst.
(*a*) Unilateral disease 3
(*b*) Bilateral disease 10 (1)
———13 (1)
3. Tuberculous salpingitis 6 (1)
—— 46 cases. 3 deaths
II.—Suppurative Conditions.
(*a*) Unilateral disease 12 (2)
(*b*) Bilateral disease 62 (2)
———— 74 cases. 4 deaths
Total .. 120 cases, 7 deaths

I realise that against any scheme of classifying such cases some objection could be urged; this one is a clinical classification based on operative diagnosis, and I have adopted it because it is a simple one, and because it shows sufficiently the type of cases dealt with. I propose to make some preliminary observations on each group before passing on to the consideration of some questions of operative treatment.

I.—Non-Suppurative Diseases.

1. *Salpingitis.*—The cases under the heading of unilateral disease present several points of interest. The main indication for operation was pain. It is noteworthy that a unilateral salpingitis is rare, as a primary condition; in Case 1. there was a return of the disease in the opposite side, and a second operation had to be undertaken (Case 2) a year and a half after the first. In Cases 7, 8 and 10 an ovariotomy had previously been done on one side, and in Case 5 a ventrofixation had been done; and it is possible that the salpingitis was a post-operative result. Case 11 was a hæmatosalpinx discovered accidentally in the course of an operation undertaken primarily for chronic retroversion. Case 3 was, judging from the history, undoubtedly gonorrhœal in origin; it is well known that gonorrhœal salpingitis is almost invariably bilateral. In the remaining three cases in this group, the origin of the salpingitis was unexplained; the remaining tube was obviously not seriously damaged, because two of the patients became pregnant subsequently. This fact has an important bearing on the question of conservative procedures, which I shall discuss later.

The cases of bilateral disease presented, on the whole, similar characteristics; the tubes were enlarged, occluded and adherent; in half the cases the uterus was in a condition of retroversion with fixation; and in several of the cases there were bowel adhesions. All the patients complained of frequent or constant pain and chronic disablement. In cases 5, 12 and 16 the appendix was involved, probably secondarily. Case 3 presented a remarkable condition, which I have not met with before or since; each tube had a distal blunt end, exactly like a vermiform appendix, and a little further out was found the proper distal end of the tube, with its fimbriæ. The appearance suggested that the tubes had been constricted and divided by adhesion bands; but no such bands were present. There was no evidence of inflammation in the tubes and I made an artificial ostium in each by making a longitudinal incision and suturing the mucous to the serous layer.

2. *Hydrosalpinx and Tubo-Ovarian Cyst.*

Hydrosalpinx, like salpingitis, is rare as a unilateral affection, and it is rather a curious instance of cases occurring in groups that three cases in this list were operated on within a few days of each other. In all three cases operation was undertaken primarily for uterine displacement, namely, for chronic retroversion, for fatal procidentia, and for fixed retroversion respectively, and the hydrosalpinx was discovered incidentally.

There were 10 cases of bilateral hydrosalpinx and tubo-ovarian cyst. I have grouped the two conditions together, inasmuch as a tubo-ovarian cyst may be regarded as originating from the fusion of the hydrosalpinx with an ovarian cyst. Operation in these cases was undertaken on account of chronic pain and disablement associated with obvious enlargement of the uterine appendages; the diagnosis before operation was "chronic disease of the appendages," for it is not possible before operation to make a definite diagnosis of hydrosalpinx or tubo-ovarian cyst. The physical signs are identical whether the tubes are distended with clear fluid or contain pus; in some acute cases with febrile symptoms it is possible to diagnose pyosalpinx, but in chronic cases of this condition there is usually no rise of temperature, and the presence or absence of pus is a matter of surmise. These cases did not present any features calling for special comment, except No. 3, which will be referred to when discussing the mortality of the operation, and none of them admitted of the carrying out of conservative procedures.

3. *Tuberculous Salpingitis.*

In the paper previously quoted, Dr. Cullingworth advocated the removal of tuberculous tubes when there was no evidence of the disease elsewhere in the system; and though some speakers in the discussion dissented from this view, it is the accepted teaching at the present day. That it may have excellent results is illustrated by the first case on the list; I saw her recently, 10½ years after the operation, and she was well and strong in every way, and had shown no further signs of tuberculosis. Case 3 was in an advanced cachectic state, with a sinus in the loin; and operation was undertaken rather with a view of giving her some relief than with the hope of cure; but she rapidly sank from exhaustion and systemic infection. Case 6 was a remarkable one, in that the disease appeared to be confined to the pelvis; the tubes were enormously distended with caseous material. But within a few weeks of the operation she developed all the symptoms of acute miliary tuberculosis, from which she died not long afterwards. The disease was bilateral in every case save one (No. 4); as the left tube in this case appeared to be quite healthy I decided to leave it, and I have not so far heard her later history.

II.—Suppurative Diseases—Pyosalpinx and Suppurating Ovarian Cysts.

Suppurative, like non-suppurative disease of the appendages, is much more common as a bilateral than as a unilateral condition; it will be observed that only 12 out of 74 or 16.2 per cent. of cases of suppurative disease were unilateral. Taking the whole series of cases, 27 out of 120 or 22.5 per cent. were unilateral.

Taking the unilateral suppurating cases first, it is rather a remarkable fact that five of them, namely, Cases 5, 6, 7, 9 and 11, were *post-partum* cases in which operation was done from three to six weeks after confinement. Yet in none of these five was there any evidence of septic infection from without conveyed during labour; they all appeared to be instances of the recrudescence of tubal disease antecedent to the labour; but I think it probable that the recrudescence was due to the disturbance of anatomical conditions produced by the rapid change in position of the fundus from the epigastrium to the hypogastrium. Such cases, of course, give the medical attendant the gravest anxiety, and may cause him to be unjustly blamed for a condition of puerperal sepsis over which he had no possible control. Another striking fact is that in 9 out of 12 cases there was suppurating ovarian cyst or ovarian abscess complicating the pyosalpinx. The cases of bilateral suppurative disease form just over a half of the whole series of cases of tubal inflammation. I cannot give precise particulars concerning the bacteriological origin of these conditions, but from clinical data I can safely say that the great majority were due to gonorrhœal infection.

Most of the cases presented somewhat similar characteristics; there was pain and disablement of long standing with subacute exacerbations from time to time, and a condition of chronic pyosalpinx was found on operation. Some of the cases, however, presented points of special interest. Only two of the cases, Nos. 25 and 36, were *post partum*; in neither of them was there any evidence of infection from without during labour. Case 36 was already in a septicænic condition when operation was undertaken as a last resource; the origin of the disaster appeared to lie in a dermoid cyst which suppurated after delivery, and perforated into the peritoneal cavity, leading to a large retro-uterine abscess. Counting this case there were in all 15 out of 62, or 25 per cent., in which pyosalpinx was complicated by a suppurating ovarian cyst or tubo-ovarian abscess. One case, No. 22, was complicated by a retro-cæcal abscess and acute peritonitis, in a young girl of 17; the association of the different conditions was difficult to explain. Case 30 was remarkable in that the uterine wall contained an abscess, and the whole uterus was in a septic condition and so rotten that it was with great difficulty that sutures could be got to hold. In Case 18 the double pyosalpinx was complicated by an extra-uterine gestation, the sac lying in the pouch of Douglas, and closely incorporated with the uterus. All the structures were in an extraordinary tangle, and the only way out was to do a total extirpation of uterus, sac and appendages. Case 44 led to an erroneous diagnosis. A few years previously I had removed by vaginal myomectomy a large fibroid lying in the vagina with a pedicle attached to and partially inverting the fundus, and completely filling the pelvis. When she presented herself again with a large pelvic tumour, apparently incorporated with the uterus, I diagnosed uterine fibroids; but it turned out that the swelling was due to greatly distended pus-tubes closely adherent to a normal-sized uterus. Case 51 was remarkable in that she was seized with sudden pain and collapse exactly like that produced by a ruptured tubal pregnancy, and that was the diagnosis on which I was sent for to operate. The physical signs were consistent with that diagnosis, but the menstrual history was not characteristic. In Case 53 a pelvic abscess was opened by the abdomen and drained by my colleague, Mr. Walter Edmunds, the patient's condition being too bad to admit of exact location and removal of the source of the abscess; a discharging sinus persisted for some time, and Mr. Edmunds asked me to take over the case as he considered that the abscess had a tubal origin. I was able to trace the sinus down to the left tube and remove the tube and sinus in one piece. The right tube was also affected. In Cases 54 and 56 the tubes presented the naked-eye appearances of caseous tuberculous pus-tubes. I had a pathological report on both cases from the West End Pathological Laboratory, to the effect that there was no evidence of tuberculosis. The condition is so unusual apart from tuberculosis that I have brought the specimens to show to the Fellows of the Society.

This group contains some of the most difficult and anxious cases in which I have had to operate; one is always confronted by the danger of injury to adherent bowel, and by the fear of infection from pus sacs rupturing during the operation. Fortunately, the latter danger is minimised by the fact that in many cases the pus is sterile; but it is not always so and in some cases conditions of acute peritoneal infection prevailed. The comparative safety with which many of these may be dealt with may properly be regarded as one of the triumphs of modern surgery.

Mortality. This question of safety leads me to speak of the mortality attendant on these operations. Taking all the cases together without regard to the question whether the deaths were preventible or not, the tables show a mortality of 7 cases in 120, or 5.8 per cent. Taking the individual fatal cases in chronological order, the first was No. 3, Table II a, in May, 1900; death resulted from septicæmia, probably to be attributed to contamination of the field of operation by the pus that was present; drainage was done through the vagina, by an opening in the pouch of Douglas. The second case was in the tuberculous group (No. 3, Table I., 3). I have mentioned the fact that the patient was already in an advanced and hectic condition. This death occurred in October, 1900. The third was in January, 1902 (No. 3, Table I., 2*b*), and may be described as a death from misadventure; the patient developed post-operative mania and while she was being fed, some food entered the trachea and she died almost at once.

The fourth was in January, 1903 (No. 5, Table II*a*). The patient was in a condition of septicæmia before the operation, and from this she died. The fifth was in March, 1903 (No. 4, Table I., 1*b*); there was a good deal of oozing from the site of adhesions, and as she was showing signs of collapse some hours after operation, transfusion was resorted to. I think it probable, looking back on the case, that this transfusion was ill-timed, and started fresh bleeding, which led to a fatal syncope. The sixth case was in May, 1904 (No. 30, Table II*b*), and death resulted from the shock of a severe operation, associated with a good deal of hæmorrhage; the difficulty in hæmostasis arose from the fact that all the structures in the pelvis were inflammatory and rotten. The seventh death, which occurred in November, 1904 (No. 36, Table II*b*), was in a case where septicæmia was present before operation, as the result of a suppurating dermoid perforating into the peritoneal cavity.

In operations of this kind some deaths are inevitable, particularly when the operation is undertaken too late, as was clearly the case in the second, fourth and seventh cases. It is probable that experience and improved technique tend to a lower mortality; at any rate, the tables show six deaths among the first sixty cases operated upon, and one death in the second sixty cases. The 74 cases of suppurative disease compare favourably with the others as regards the mortality, with a fatal percentage of 5.4 against 5.8 on the whole series. The last fatal case was just 2½ years ago; but just as I do not seek to extenuate the failures, so I do not claim credit for the successes, for I recognise that there are times when one is aided by good fortune, just as there are times when one may have a succession of cases foredoomed to failure. While on this subject I may express my conviction that if one's work is done with an eye to statistics, it is conceived in a wrong spirit and will prove faulty in practise. I take it that all that is required of us is that we should treat each individual patient in such a way as seems likely, taking all circumstances into consideration, to give the best chance of saving life and restoring health in that case, remembering that the issues of life and death are not given unreservedly into our hands.

The Scope of Conservative Surgery.—On this important question I accept it as a fundamental axiom that every operator must be allowed complete discretion as to how much or how little he will do in any case ; and so I will here give only my own impressions and practice without pretending to lay down the law for others. My first belief is that it is not necessary to remove the uterus in every case in which both tubes and ovaries are removed. In most cases the removal of the uterus means a more prolonged and severer operation ; and if the uterus is not seriously affected, it does not harm when left *in situ*, but, on the contrary, helps to preserve the integrity of the pelvic floor. In some cases in which endometritis has been present, curetting has been subsequently required ; this was done in several of my cases, and I do not regard the possibility of this contingency as a sufficient reason for a routine removal of the uterus. I shall refer to this point again when speaking of technique. In the second place I have but little confidence in the value of salpingostomy in cases where the tubes are occluded by the inflammatory process ; and even when the abdominal ostia are still patent, I prefer not to leave tubes that are obviously in a condition of chronic or sub-acute salpingitis ; because it appears to me that such tubes have lost the power to be functionally useful, and if they are left behind, a probable source of future trouble remains. I regard such tubes as I regard the appendix, and consider that the patient's interests are best safeguarded by their removal. Thirdly, when the appendages of one side are not obviously diseased I prefer to leave them untouched, even though the opposite tube may contain pus. It is true that this course may occasionally necessitate a second operation ; but on the other hand there is a definite chance that the appendages that are saved may be serviceable, as in two of my cases where pregnancy followed the operation. I think that the value of conservative surgery in these cases is not nearly so problematical as it is when applied to tubes that are obviously affected.

Fourthly, it seems to me to be good practice to leave the ovaries whenever it is possible, even when the corresponding tubes are so diseased as to require removal. For although the possibility of child-bearing may be gone, convalescence goes on more smoothly when a normal ovary is left, and the patient is saved the disagreeable sequelæ of an artificial menopause. In many cases, of course, both ovaries are so intimately involved in the inflammatory process affecting their tubes, that to leave even one of them is out of the question. But in such cases there is also less reason for saving them, because I believe that the removal of diseased ovaries has far less effect on the system than the removal of healthy ones.

Technique of the Operation.—In most of these operations the most serious difficulty that presents itself is the *separation of adhesions*. Coils of intestine, both small and great, may be intimately adherent to pus-tubes and to the back of the uterus. Sometimes the peritoneal surface of the bladder is involved, and the utero-vesical space is completely obliterated ; and, indeed, the summit of the bladder may overlie the fundus and be so adherent to coils of bowel behind it that the uterus is quite buried. The adhesion of bowel to pus-tubes sometimes represents an attempt at the evacuation of the abscess cavity through the intestine, and the wall of the tube may be, in fact, perforated, so that the separation of adhesions may be the signal for a copious discharge of pus into the field of operation. As a preliminary step, therefore, before the separation of adhesions is commenced, swabs should be packed round in such a way as to shut off as much as possible of the peritoneal cavity from the field of operation; and if a pussac is tapped, the pus should be mopped up as quickly as possible. In separating adhesions, the body of the uterus should always be taken as the starting point ; by working down behind it the best planes of cleavage will be reached. When the bowel has been cleared off from the back of the uterus and tubes, the next thing is to peel off the tubes from the back of the uterus and broad ligaments, and this is best done by working from below upwards. Before this is begun, it is often a good thing to isolate the outer extremity of the broad ligament and place a clamp on the ovarian artery, because the structures are often brittle, and it is easy, when peeling the tubes off from below, to tear through the ovarian artery, which then retracts in such a way as to make it a very difficult matter to secure it, and meanwhile troublesome hæmorrhage goes on, which obscures the field of operation and causes great delay. When the tubes and ovaries have been freed, the way of dealing with the pedicle may vary according to the extent of the disease in the tubes and the amount of infiltration of the broad ligament. When the uterine end of the tube is relatively unaffected, and the broad ligament is not infiltrated, it is often sufficient to treat the pedicle by transfixion, as in ovariotomy, leaving a short stump of the tube. As a precaution the tubal stump may then be swabbed over with some antiseptic, to minimise the chance of infection. When the uterine ends of the tubes are distended with pus, and the broad ligaments are infiltrated, it is a good plan to cut through the broad ligament from without inwards, each cut being preceded by the application of a clamp below the line of division. When the tubal attachment to the uterus alone remains, it should be cut right out of the uterine cornu by a V-shaped incision, and the edges of the wound in the uterus brought together by mattress-sutures. This process of *resection of the tubes* was adopted in nine of my more recent cases. A chain of sutures is then passed along the broad ligaments below the series of clamps.

When the tubes have been enucleated from the back of the uterus there is apt to be some troublesome oozing, which often arises from some vertical tear in the angle between the uterus and broad ligament. This is best dealt with by a mattress suture bringing the edges of the tear together ; and it should be done before the rest of the broad ligament is sutured because otherwise the tear is buried in a hollow and is very difficult both to see and to sew.

When the uterus is so adherent to the tubes that the removal of the latter leaves a badly damaged and bleeding uterine surface it is often both safer and quicker to remove the uterus than to attempt to stop the hæmorrhage merely by ligatures. The uterus will also require removal in certain other conditions, such as when it is septic or the seat of fibroids. I had occasion to remove the uterus as well as the appendages in five cases, one of which was the case of septic uterus before-mentioned. In one case (No. 11, Table II *a*), there was an abscess cavity involving the right tube and a part of the right uterine wall ; and the whole of the right cornu of the uterus was removed with the tube.

When the tubes have been removed, there is sometimes a tendency for the uterus to fall back into the pouch of Douglas ; and a good deal of subsequent pain and discomfort may be avoided by fixing the fundus to the anterior abdominal wall.

Injuries to bowel may require to be dealt with, by carefully suturing a rent in the serous coat when this is alone involved ; or by more extensive suturing or even by resection of a piece of bowel when the cavity of the bowel is opened up. Even when every precaution is taken, a fæcal fistula may follow ; of this I had several experiences. Such fistulæ almost invariably heal spontaneously. Less frequently the bladder wall may be damaged and require suturing.

There are only two other points of technique to which I wish to refer, namely, *flushing* and *drainage*. The conclusion at which I have arrived with regard to flushing is that its use should be limited to cases of tuberculous salpingitis with hydroperitoneum. Here the whole peritoneal cavity or such part of it as is involved in an encysted collection of fluid, is affected, and flushing with saline solution can do no harm, and I think it is likely to do good. In all other cases I believe that flushing entails extra risk, by conveying septic matter to non-infected regions. With regard to drainage, I have come to the conclusion that it is best avoided in tuberculous cases ; after the flushing out, I think it is well to mop out the fluid and close the abdomen. In other cases, drainage has a decided field of usefulness, but there are cases where it is better omitted. The practice which I have formulated for myself is that when there has been no contamination by pus, and adhesion sites are not oozing, and the bowel has not been damaged, the abdomen can be safely closed. When there is a tendency to oozing, I put in a gauze drain to serve as a warning in case of bleeding; it is removed at the end of twenty-four hours if no bleeding has occurred. When bowel has been damaged, a gauze drain is left in for forty-eight hours or a little longer, so that if a fæcal fistula should become established there will be a means of exit for the fæcal matter. In cases of acute septic peritonitis, I use a large rubber-drainage-tube, which is left in for forty-eight hours, and at the end of that time a smaller one is put in if necessary. In cases of this kind we have a valuable help to treatment in what is known as *Fowler's position.* Almost as soon as the patient has recovered consciousness she is placed in as upright a sitting position as possible; by this means the septic matter has the least chance of reaching the vulnerable area of the peritoneum, which is the under-surface of the diaphragm; and the success of the treatment is further assured by repeated rectal injections of saline solution. I do not wish to discuss at any length the after-treatment of these cases, but I should like just to say that in my opinion the best results in cases of septic peritonitis are obtained by the administration of calomel in small repeated doses of $\frac{1}{6}$ of a grain given every hour for five or six hours, on the day after the operation; and by the most strict abstention from morphia in any form.

In order to be really complete, a consideration of the surgical treatment of inflammatory diseases of the uterine appendages should comprise a statement of after-results; but this is in itself such a large and important question that it requires to be dealt with separately. If further apology be needed for leaving it out of present consideration, I may say that for many years I have been collecting data on this subject, which I hope to deal with on some future occasion.

In conclusion, if the personal note has been rather too dominant in these remarks, I can only plead as my excuse that the scope of my paper and the time at my disposal did not admit of much more than a narration of my own experience.

A MEDICO-LEGAL DEFINITION OF INSANITY.

By CLEMENT H. SERS, M.R.C.S., L.R.C.P.,

Brighton.

THE opinion entertained by so many that there exists an insuperable difficulty in rendering a satisfactory definition of insanity requires qualification, as the idea may after mature thought turn out to be untenable. That the question is one of paramount importance in a medico-legal sense, so as to prevent confusion of thought when the alienist and jurist are confronted one with another, and hence to induce mutual understanding there can be no gainsaying.

It will be observed that the real or imaginary difficulty in defining the word insanity, assuming there is a difficulty, is by no means limited to this identical word, and this, for the obvious reason that very many other qualifying words (if indeed, not all) admit of two or more meanings, on account of which any given word generates different ideas according to the grade of mind. For example, the common conventional term "Christian," one person will insist upon defining this as one who believes in the christian creeds as propagated by an exclusive sect. Another, as in the case of the late Mr. Gladstone, would define it as a belief in the founder, and yet a third probably endowed with nothing beyond a philanthropic and benign disposition, and may be, morally speaking, as sound as a roach, equally insists that he too is embraced by the same definition, although concerning any actual belief in creeds, he may be next door to an infidel. We may also remember the difficulty in defining midwife. Thus we see what different shades of thought give colour to the same expression.

It should, perhaps, once for all be admitted that no scientific or psychological definition could be advanced which would ensure general assent. Neither would it serve any useful purpose. Certainly not for medico-legal purposes. The reason whereof as everybody knows is that mental processes are so complex and incomprehensible in health. Moreover, the connection between what we call mind and matter so inseparable and subtle, that it would be an impossible attempt to unravel these in diseases, or to express in the same breath the numerous phases of mental aberration. This consideration affords no reason why a medico-legal definition cannot be formulated which, except amongst sophists and strawsplitters, might create mutual understanding between lawyers and medical men.

Now a definition after all said is no more or less than an attempt at the most lucid explanation of a general term or word according to the definer's meaning and within compass of as few other words as possible. Consequently our aim is, or should be, to achieve this. By insanity is meant in its *broad* acceptation (and in this respect jurists, alienists, and even the general public are on equal ground) to denote the distinction in conduct and ideas of one or more individuals compared to others, of course of the same nationality, some of whom in contradistinction, are designated as sane, and others insane. The fact that jurists and legislators will not altogether agree to our selection or classification; on the contrary arrange their own category, regarding some sane whom alienists regard as insane, is no fault of ours, and is altogether another question, otherwise some crimes, needless to specify, might by the general consensus of expert medical opinion absolve the culprit from moral responsibility. For this there is no remedy, so if jurists in their wisdom think wise to overrule those who have made mental conditions their special study and avocation, indeed, who may be said to have spent their lives in company with the insane, we can only hope more enlightened times may turn such from the error of their ways.

Now to come to the point as to a medico-legal definition, the writer might refer to a correspondence in the MEDICAL PRESS AND CIRCULAR of July 13th, 1904, under the headline "Insanity, a practical definition," in which he then attempted to define insanity for the purpose in question *as a morbid condition of mind requiring supervision*, but which might perhaps be better described as a *morbid condition of mind subject to legal intervention.* Several notorious cases concerning abnormal minds have since occurred. Moreover, Dr. Savage, in his lecture before the Royal College of Surgeons, published in the *Lancet*, March 30th, offers some significant and noteworthy remarks, both of which circumstances, indeed, appear to give countenance to the suggested definition, and, indeed, revived the subject in the writer's mind. Thus Dr. Savage, without discussing the question of definition, although incidentally criticising the articles of the *Times* writer on insanity says, "The true difficulty is that the disease insanity as a definite entity does not exist, yet one might almost conclude from the elaborate articles which have appeared in our leading daily journals that it does, and that it is as definite in its symptoms and origin as cancer and pulmonary consumption."

It will be observed, therefore, that the definition advanced makes no pretence of revealing any specific disease or "definite entity." Nor does it refer to causation or pathology, and so far conforms to Dr. Savage's enunciation and teaching. Indeed, for purely medical purposes it might almost suffice to define insanity as *a mental symptom of disease*, somewhat analogous to jaundice, regarding both as mere symptoms. Neither does the definition necessarily imply personal restraint, so would include the recent case of a nobleman, when the law intervened with regard to direction of affairs, at the same time granting personal freedom. Further, as in the case of a very intelligent bachelor lawyer, a landowner, who was prepossessed with the idea that there was an intrigue to poison him, who nevertheless conducted his own household and affairs with admirable circumspection, the law might, in such a case, and no doubt would, under favourable circumstances, remain inert. Supposing, however, such a man executed a will depriving his next-of-kin of their natural expectations, the intervention of the law might be sought, and the will invalidated in favour of the surviving heirs, the definition meeting the exigencies of the case. The report in the daily papers of a medical witness having been asked "What is insanity?" and expressing his inability to reply, would probably prejudice a jury as to the value of the evidence which might be tendered, whereas an answer to the question "I mean by insanity a morbid condition of mind subject to legal intervention" might release a witness from the loophole leaving him free to explain the morbid conditions.

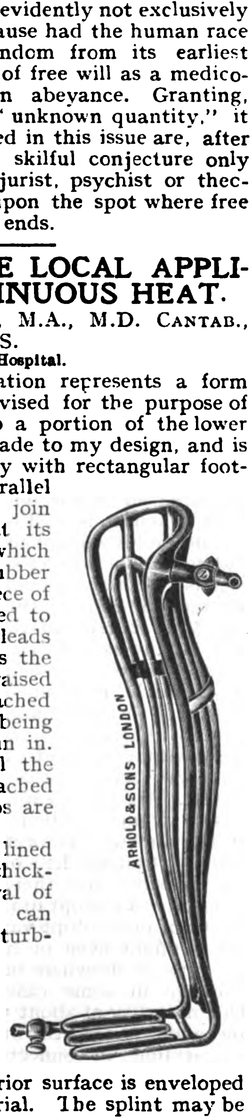
In conclusion, there can be no doubt that the most thorny point within the whole range of medical jurisprudence a witness may be called upon to speak definitely is: Is, where no definite delusions exist, the supposed insanity hinging upon moral responsibility? That this responsibility or will power is a limited capacity there can be no two questions, as numbers of crimes are committed through the influence and persuasion or instigation of others, but for which such crimes had never been committed. Further, the law recognises this limitation in placing meditated and unpremeditated crimes in different categories. Moreover, freedom of will power is evidently not exclusively a theologian's hypothesis because had the human race maintained complete heathendom from its earliest transit till now, the question of free will as a medico-legal one would still be in abeyance. Granting, therefore, this freedom an "unknown quantity," it follows all cases solely involved in this issue are, after all said, subject to the most skilful conjecture only because neither the alienist, jurist, psychist or theologian can place his finger upon the spot where free will begins, neither where it ends.

A SPLINT FOR THE LOCAL APPLICATION OF CONTINUOUS HEAT.

By J. F. HALLS DALLY, M.A., M.D. Cantab., M.R.C.S.

West London Hospital.

The accompanying illustration represents a form of splint which has been devised for the purpose of supplying continuous heat to a portion of the lower limb. The splint has been made to my design, and is of the posterior gutter variety with rectangular foot-piece, and is made of parallel lengths of lead piping, which join a marginal tube, having at its proximal extremity a tap, to which may be attached an india-rubber tube and funnel. Another piece of indiarubber tubing is attached to the tap on the foot-piece, and leads into a receiver which catches the overflow. The funnel is raised above the level of the tap attached to the foot-piece, both taps being open, and boiling water is run in. As soon as the splint is full the water runs out of the tube attached to the foot-piece. Both taps are then closed.



The splint is previously lined with flannel to the required thickness, and by periodic renewal of the hot water supply, which can be accomplished without disturbing the patient, the flannel is heated, and continuous dry heat thus applied to the limb. This latter is immobilised in the splint by some form of suitable appliance, and, if necessary, its anterior surface is enveloped in some non-conducting material. The splint may be also used for the continuous application of cold after the manner of Leiter's coil. Reference to a case of post-typhoid venous thrombosis, under the care of Mr. Keetley, in which this splint was used with advantage for the purpose of supplying continuous heat, will be found in the *West London Medical Journal*, Vol. XI., 1906, p. 330.

THE OUT-PATIENTS' ROOM.

ROYAL FREE HOSPITAL.

Tuberculous Epididymitis with affection of the vesicula seminalis.

By Joseph Cunning, B.S., F.R.C.S.

Amongst the out-patients was a man, æt. 19, who complained of a swelling in the left testicle. He was quite well until nine weeks before, and since then he had noticed a gradual painless enlargement; there was no history of urethral discharge or of any injury. On examination the epididymitis was enlarged to about two inches in length; it was hard and nodular. The testis itself was apparently not affected. There was no fluid in the tunica vaginalis and the scrotal tissues were not adherent to the epididymis. The structures of the cord were thickened but no special thickening of the vas could be detected. The rectum was then examined, and the left vesicula seminalis was found to be thick, hard and nodular. Mr. Cunning said that the diagnosis of swellings of the testicle usually rested between three things: tubercle, syphilis and new growth, excluding of course acute inflammatory affections. With regard to new growth, such enlargements were more commonly found in the body of the testis, were uniform in shape rather than nodular and, of course, do not affect the vesiculæ seminales; the same remarks would apply to syphilis, excepting that in this disease the swelling was generally a localised one in the testis and not a general enlargement of the whole organ, and besides, other signs of syphilis were always present. With reference to tubercle, it could be laid down as a dogmatic law that chronic enlargement of the epididymis was always tuberculous. A point to be considered in differential diagnosis was the thickening of the vas; if this were thickened the symptom generally meant that the cause of the testicular swelling was tubercle, but it had been found in a good many cases that, although the vas was found to be uninvolved, the vesicula seminalis was already diseased; for this reason a rectal examination should never be omitted. To examine the vesiculæ seminales the knee-elbow position would be found the most suitable, for, with one finger in the rectum and the other hand on the abdomen, the vesiculæ seminales can be felt very thoroughly. It would be found useful, he pointed out, in a doubtful case to express the contents of the vesicula seminalis into the prostatic urethra and then into the membranous urethra; next to get the patient to stand up, and then express the secretion into a clean test tube and examine the contents for tubercle bacilli. On inquiry into the symptoms of the case under consideration there was no pain or frequency of micturition, which roughly indicated Mr. Cunning said, that there was no spread of tuberculous disease to the base of the bladder. The treatment of such cases was, he remarked either palliative or operative: if the disease was confined to the epididymis it was reasonable to try the effects of hygiene and tonic treatment, which would consist in the patient living in the fresh air and sunshine and having at least three pints of milk per day, added to the ordinary diet; in addition, the patient ought to be inoculated with tuberculin R. 1–800 to the milligramme, according to the method of Sir Almroth Wright. Some cases certainly improve under this treatment, but a careful watch must be kept for any signs of extension of the disease; if this occurred no more time should be wasted, but resort should be had to surgical means, for the path of extension from the vesicula seminalis is to the bladder, and the tuberculous bladder is a much less hopeful case to treat than disease that is limited to the genital tract. In the present case Mr. Cunning proposed to at once excise the testicle, and the vas, as far as possible, and then proceed by a transverse perineal incision to excise the left vesicula seminalis. This latter part of the operation, he said, involved a very deep incision in the perineum, separating the prostate from the rectum until the vesicula was reached; the operation was helped by the presence of the disease, as the thick hard nodular vesicula was so much more easily recognised than the normal one.

OPERATING THEATRES.

ROYAL FREE HOSPITAL.

Strangulated Congenital Inguinal Hernia in an Adult.—Mr. **Willmott Evans** operated on a man, æt. 42, who had been admitted for severe pain and vomiting. He had suffered for several years from an inguinal hernia on the right side, and he had worn a truss; the hernia had always come down when the truss was removed, but had been readily kept up as long as the truss was in good condition. A few months before admission the truss had become worn out, and though the patient still wore it, it did not suffice to retain the hernia when he made any great exertion; he was careful, however, to return the hernia as soon as possible after it came down. On the morning of admission, he had strained at stool, and whilst straining he had felt a sudden sharp pain in the hernia which came down in spite of the truss. When he attempted as usual to return the hernia, he found it would not go back; he had repeated two or three times the attempts at reduction. Within three or four hours vomiting commenced, though it was never urgent. As the pain continued, he came to the hospital in the afternoon, and was at once admitted. On examination there was found in the right groin a very definite swelling about the size of a hen's egg, with its long axis extending downwards and inwards internal to the pubic spine. There was no impulse on coughing, and the swelling was irreducible. The bowels had acted at the time of the onset of the symptoms, though the motion was constipated. The patient said he had passed no flatus since the initial attack of pain. The vomiting was slight, but it was readily evoked at any attempt at taking fluid. The man having been anæsthetised, a two-inch incision was made over the external ring; the intervening structures were cut through and the hernial sac was laid bare. When this was opened, the bowel was seen to be markedly congested, but it was readily returned after the neck of the sac had been enlarged by means of a herniotome. It was then seen that the cavity of the sac extended downwards by a narrow channel into which it communicating with the cavity of the right tunica vaginalis. The upper portion of the sac was dissected out, separated from the tunica vaginalis, and ligatured as high up as the internal ring. It was then cut through a short distance below the ligature. The skin wound was closed and dressed. Mr. Evans said that the anatomical arrangement of the hernial sac showed clearly that its presence was due to the non-obliteration of the funicular process, although attempts had been made at closure by the process, as was shown by the narrowing of the channel for an inch and a half above the testis, and the narrowness of the internal ring. When strangulation occurs in inguinal hernia, he pointed out, it is not rare to find that the hernial sac is really a partial or complete variety of congenital inguinal hernia, and not acquired, and the cause of this special proclivity to strangulation observable in congenital inguinal hernia of adults is, without doubt, chiefly due to the spontaneous attempts at closure of the funicular process; though these attempts have not sufficed entirely to obliterate the process, they are sufficient to lead to such narrowing of the canal that strangulation of the bowel passing through it is very liable to occur. When the sac of an inguinal hernia is entirely "acquired," the neck is certainly wider and strangulation is much less likely to occur; In the child, too, the softness of the surrounding parts tends to prevent such firm nipping of the included bowel as is needed to produce strangulation, therefore strangulation of congenital inguinal hernia is most commonly seen in the adult. With regard to the treatment pursued after the strangulation had been relieved and the bowel returned, he thought it worth while to say a few words. In his opinion it is not necessary in these cases to perform any of the recognised methods of radical cure, for, if the sac be ligatured as high as possible and the stump pushed back, recurrence does not occur, as the hernia itself was the result not of any true weakness of the abdominal wall, but it was induced by the presence of the unobliterated process. As soon as that process is removed no inducement for the recurrence of the hernia exists; therefore complete removal of the sac is amply sufficient for a radical cure.

The further progress of the case was uneventful, the patient leaving the hospital in the third week.

TRANSACTIONS OF SOCIETIES.

THE BRITISH GYNÆCOLOGICAL SOCIETY.

Meeting held Thursday, May 9th, 1907.

Dr. Heywood Smith in the Chair.

Dr. A. E. Giles demonstrated two specimens of salpingitis referred to in his contribution and containing caseous pus. At the operation he thought the condition was due to tuberculosis as he had on non-tuberculous tubes. The pathological report, however, showed no sign of tuberculosis.

Dr. **Giles** then read his paper entitled

OBSERVATIONS ON THE SURGICAL TREATMENT OF INFLAMMATORY DISEASES OF THE UTERINE APPENDAGES,

based on a series of 120 cases, which will be found in full on page 560.

The **Chairman** said when papers were read giving details of work done, the personal element necessarily entered largely into the matter. Practitioners of the speciality learnt from each other, according to their personal idiosyncrasies and aptitudes, the ways of doing the operations, and in that way surgery was advanced in minor details.

Dr. **Machan** desired to express his thanks personally for the tables which had been placed before them. He had found the author's paper much more interesting because he had been able from time to time during the reading of it to turn to particular cases referred to. With regard to the ultimate results, there was no reason to expect that they would be less favourable. There was no doubt that gonorrhœa was the cause of an immense number of the cases of suppurative disease of the appendages. At the same time the difficulty of diagnosis in some of the cases of salpingitis or pyosalpinx and ectopic pregnancy had been insisted upon in various cases, and was a very important matter. He was disappointed to find that the author was so strong an adherent to the method of drainage by the abdomen in preference to that by the vaginal route. Drainage had of late been discarded in every case possible, but there were cases in which it was imperative to adopt drainage, and in certain cases one must not only adopt vaginal and abdominal drainage, but it might even be necessary to make incisions in the loins or elsewhere in order to secure perfectly free drainage in some cases of suppurative peritonitis. The mortality of about 5.8 per cent. seemed to be very low, and it was worthy of remark that this low mortality was attained in connection with conservative surgery. With regard to the remark about liberating adhesions from below upwards, he had noticed in recent literature that the difficulties were greatly removed if we began from below and then worked upwards. With regard to excision instead of simply cutting off the tube, excision of the tube from the cornu of the uterus was a most important point, and it rendered operation much safer for the patient. In reference to the remarks concerning hæmorrhage, sepsis, the healing of a fæcal fistula and especially about the use of calomel immediately after abdominal operations, he thought we all agreed about those points. There could be no doubt that the danger of "peritonism" was much less if calomel was administered comparatively early after the operation.

Mr. CHARLES RYALL said he discarded the suprapubic method of drainage some years ago, and resorted to vaginal drainage because whenever a drainage tube was left in there was weakness in the abdominal wall, where there might be a post operative hernia. He had seen so many cases in the past in which drainage was resorted to, by the abdominal wall and was followed by hernia, that he decided after some experience to give it up. It was easy to make a counter opening, and the simplest way was for the surgeon to do it himself, placing the scalpel flat on the fingers and passing it into the vagina. The danger of the vaginal route was that there was liability to sepsis, and that the vagina could not be kept aseptic. In a normal individual, if a posterior colpotomy were performed, there was no reason why sepsis should spread from the vagina into the abdomen.

Dr. SMALLWOOD SAVAGE said he had seen many post-operative herniæ, and his opinion was that if there was any other way of draining than by the abdomen such should be adopted. He believed that some cases as those of acute pyosalpinx should be treated by vaginal incision and drainage, because in a certain number of these cases the tubes and ovaries would assume normal functions, and many cases when treated in that way had had children subsequently. So that the sacrifice implied in a radical extirpation of ovaries and tubes was not in all cases necessary in pyosalpinx. There was a valuable medical treatment which Prof. Taylor brought before the Society some years ago, in 1899 he thought, and was still practising it with good effect. A great many cases of salpingitis were due to either pure gonorrhœal infection, or to a mixed infection of gonorrhœa and syphilis. Professor Taylor had found by experience that by giving mercury with iodides, a certain number of such cases, if not all of them, could in a reasonable time be cured. Of course, it was necessary to use care in the treatment because it was possible to miss a case of pyosalpinx. But where a patient could be given that medical treatment and there was improvement, how much better to leave that woman who was probably young with her tubes and ovaries. The author had said that pyosalpinx was probably the cause, or might possibly be the cause, of lighting up an inflammation *post partum*. He would suggest that inflammation of the pelvic peritoneum and of the different parts in the pelvis, was due either to gonococcus, or to a mixed infection, subsequently, or an infection *post partum* from the staphylococcus, which had passed through the uterus. The infection due to the gonococcus affected chiefly the tube, and might seal it up, when it became thickened, and then perhaps formed a pyosalpinx. But the infection which came *post partum* travelled through the uterus and through the lymphatics to the ovaries, and the appearance seen at operation was quite different. In the one case the tube was perhaps quite closed and contained pus, whereas in the other case the ovaries might be enlarged with follicular cysts, or it might be œdematous, and if there are any adhesions it was apart from the tube, rather attaching the ovary to the back of the uterus, or perhaps even the ovarian abscess was found. Those two clinical conditions were distinct.

Dr. MCNAUGHTEN-JONES said the battle was being waged with regard to pelvic surgery generally and that battle centred round one figure, whose name at that time was in every mouth, and who long before the period referred to by Dr. Giles,—nearly twenty-five years ago, after his classical paper was read in London on diseases of the ovaries and tubes—advocated removal of the adnexa for certain conditions. He referred to the late Mr. Lawson Tait. He liked always to pay his tribute of admiration to Mr. Lawson Tate, to whom was due the initiative in the surgery of the ovaries and the Fallopian tubes. The author referred to hæmatosalpinx, but he did not say in the paper whether that was in his opinion associated with ectopic gestation, or state that there was no evidence that it was, and he took it that Dr. Giles held the view that hæmatosalpinx occurred apart from ectopic gestation, a view in which he himself concurred, and in support of which he had several times brought forward cases to prove. Others were of opinion that hæmatosalpinx never occurred without ectopic gestation. Several times throughout the paper he noticed that Dr. Giles used the term "tubo-ovarian." He would like to hear whether those were true tubo-ovarian cysts. He thought the term should be limited distinctly to those cases in which there was a sac into which the Fallopian tube directly opened. He (Dr. Macnaughten-Jones) had met with one case of primary tuberculosis of the ovary without any affection of the Fallopian tube; he had met with two cases of primary tuberculosis of the tube and both women were alive now, though both were operated on several years since, and one of them had had children since. In each of those cases only one side was affected. The point made by Dr. Giles about the blunt end of the tube was a very interesting one. He had himself figured and shown at the Society a tube exactly similar to that, a constricted tube with a blunt end such as Dr. Giles had described, and in which there was no evidence of adhesion causing contraction of the tube. In Dr. Giles's case he took it there was an extension beyond the abdominal end, which was remarkable. Those cases where the tube was inverted on itself were very interesting and rare. In old interstitial salpingitis with great thickening of the tube, we had the same blunting and closure. In the cases he referred to there was not fluid in the tube. In some there was a hæmatosalpinx, the outer end of the tube being closed in the same way.

With regard to gonorrhœa, he believed that in many cases, assuming a married woman, neither husband nor wife had any suspicion of any infective condition arising from gonorrhœa, it had been a latent gleet which possibly had lasted for several years. With regard to all that had been said as to the difference between *post partum* gonorrhœa and gonorrhœa arising from direct infection, of that he had no experience in regard to the exact pathological distinction, but in a case which he brought forward at the Obstetrical Society he had the opportunity of seeing in the living what occurred in a case of recent gonorrhœal infection. It was a case in which he emptied the uterus for profuse gonorrhœa, and removed an encephalic fœtus; after dressing the uterus for some time, and when he thought she was well, she developed general peritonitis. He found the two Fallopian tubes full of pus. Of course the presence of the gonococcus had been previously determined. Lining the peritoneum on either side and parts of the broad ligaments was a soft layer of lymph, which was proved to be gonorrhœal, and which he peeled off with gauze. The tube was afterwards examined and found to contain a quantity of gonorrhœal pus. He could then see the pus exuding from the fimbriated ends of the tube. That was the only case in which he had the opportunity of seeing the pus exuding from the tubes. He removed both tubes and ovaries. The patient recovered and had no subsequent trouble. He next referred to Dr. Giles' seven deaths, because that was a matter of great importance. One took it for granted, and in fact one knew that every aseptic precaution which was possible or conceivable was taken. Still, sometimes it happens that a patient is lost, and it is always satisfactory to hark back in such an event and see if possible whether there has been any hitch from beginning to end in connection with the operative technique, which might account for the sepsis which was present. He confessed that generally in cases in which he had lost a patient he could detect some flaw or other in some detail on the part of either himself or assistant or the nurses. Sometimes it was the post-operative management which led to sepsis. Still we are able to console ourselves with the reflection that these are autogenetic cases in which we can trace no cause for the onset of septic conditions. But it was a remarkable fact that Dr. Giles recorded among his cases of seven deaths three that were directly attributable to septic peritonitis. With regard to the case of acute mania, it was possible that in that case also the mania had a septic origin. If so, that would give four cases of death from sepsis out of seven fatalities. In one case no cause of death was given. There was also one case of shock. What did Dr. Giles think led to the shock there? Shock was a general term, and it was difficult to say precisely what it was and what it was not. It must be understood that he was confining his observations to operations on the adnexa and the pelvis, in which one source of sepsis was the freeing of some septic fluid in the pelvic cavity. That was unavoidable, and the precaution which Dr. Giles referred to, of carefully packing off and so isolating any possible diffusion of fluid from the pelvis to the general peritoneum, was one which every gynæcological surgeon adopted. Still he thought that often by means of needles or the gut, or whatever suturing material was used, the operator carried sepsis to the peritoneum. But apart from those unavoidable sources, there was one which he thought was a frequent source of pelvic sepsis. This occurred where one had to deal with adhesions at the left side of the pelvis, and where we encroached on the sigmoid and injured it, thus opening up sources of contagion from the sigmoid and rectum and transudational conditions in which the bacterium coli passed into the pelvis and gave rise to sepsis. He quite agreed with Dr. Giles with regard to the technique which he described. Much had been said about drainage. He (Dr. Macnaughten-Jones) hardly ever drained. With regard to the cases themselves it appeared that in only a few cases of the series did Dr. Giles remove the appendix. There was another most important point connected with pelvic surgery. When he was in Frieburg last year, he found it to be the practice of Krönig in every case to remove the appendix unless by doing so the operation was unduly prolonged and that it added thus to the risk. It had certainly occurred to him (Dr. Macnaughten-Jones) that it was better to do so than to have subsequently to remove an adherent appendix in a case in which there did not appear to be any necessity for touching it at the time of operation. To examine the appendix in every case where we have to remove the adnexa was a most important step, and he thought that in any case where there was reason for suspicion of danger, such as a long appendix dropping into the pelvic cavity, it was most important to remove the appendix. There were so many points in connection with the paper which it was tempting to dilate upon that he had to apologise for taking up the time of the Society to the extent he had. He joined with what Dr. Macan had said respecting Dr. Giles's paper: it was one of those valuable contributions in which actual facts were recorded, and the remarks which the author made on the cases were thoroughly practical, and he was certain they would be endorsed by any abdominal or gynæcological surgeon.

Dr. R. T. SMITH desired to ask the author about the three cases in which the operation was done *post partum*. Those were exceedingly important, and it would be better if cases of that sort were published *in extenso*; they were cases which caused regret to the surgeon whenever they occurred in practice. With regard to case 5, in Table II., left tubo-ovarian abscess, adhesion and ulceration of sigmoid, septic peritonitis, removal of left appendages, suture of sigmoid, death from septic peritonitis, he asked whether those abscesses existed before the labour or whether they were in consequence of the labour, or was it known in that case that there was disease of the pelvic appendages before the confinement. He wished to know whether serum was used? He had also felt that the one case of tuberculosis was particularly interesting, and he noticed that Dr. Giles said he removed the tube on only one side. He would like to know whether, in that case there was any ascites, and also whether the case was drained. He did not believe leaving a tube in for purposes of drainage for twenty-four hours would cause a hernia.

Dr. SLIMON said he would like to mention a case which he had seen during the last two or three weeks which bore upon the author's Table II. Three weeks ago he was asked to see a lady fifteen days after her confinement. She had a normal labour, and up to the fourteenth day her temperature had been normal. On the fourteenth day her temperature rose to 102°, and on the morning of the fifteenth day it was 104°. He examined the patient and found her uterus quite normal for the time; there was no discharge, the lochial discharge having ceased seven days before. The uterus was one inch longer than it should have been, but on the left side she had a distinct swelling, with tenderness. Per vaginam there was felt to be distinct fulness and tenderness, and as he considered that the case was urgent he advised the friends to permit him to open her abdomen. This he did, and found the left Fallopian tube full of pus, almost close to the uterus, and he removed it and the ovary. He drained it for twenty-four hours, and then removed the drain. That occurred three weeks ago. He saw her last Saturday and she was practically well. In twenty-four hours the temperature had dropped to 101°, and in the second twenty-four hours it had fallen to normal.

The CHAIRMAN said it would be interesting to know what was the proportion of gonorrhœal cases in those that were unilateral. One supposed that the virulent infection of gonorrhœa passing into the uterine cavity attacked both tubes with equal facility. With regard to the question of the removal of the uterus, he thought there was another reason why the uterus should be preserved if possible. He had known cases in which ovaries had been removed only and in which the patients had retained their sexual function and sensations quite as much as they had them before. Some of them have said that it had been increased thereby. But when the uterus had been removed as well as the ovaries the sexual appetite was almost entirely or completely obliterated. With regard to double ovarian trouble even where there might not be enlargement, but where there was suppuration, there arose the question of excision of some portion of one ovary even if the patient came before one with the idea that both ovaries might be advantageously removed, because in young people even a scrap of ovarian tissue left behind was able to give rise to an ovum which might possibly become fertilised. With regard to choice of route for drainage, he had only to say that the vaginal route seemed to be a little more risky. One cut into the vaginal areolar tissue, and that tissue was very liable to take up septic inflammation, and therefore it was rather an additional source of mischief.

Dr. GILES, in reply, said he preferred the abdominal route for drainage, but admitted he might be wrong in so doing. The main reason he did not like vaginal drainage was on account of sepsis. His second objection was the difficulty there was in keeping a drainage tube in the vagina, and passing it into the place where it was wanted. But after a tube was placed in the abdomen it remained there until it was desired to remove it. He had practised drainage in only two or three cases in his whole series, *i.e.*, in cases of definite septic peritonitis of the acute type. For the rest the drainage he used was for cases in which there had been oozing or where there had been injury to bowel. The gauze was removed in twenty-four to forty-eight hours, and then the abdominal wound was closed up completely. Sometimes he put in a loose stitch to be tied when the gauze was taken out. A plan which was sometimes useful was before taking the drain out to drop a little peroxide of hydrogen on it, which seemed to free the gauze in a remarkable fashion. He much appreciated Dr. Macan's remarks, as there was no man in the Society who had a more comprehensive and profound knowledge of current literature. Dr. Macan as long as required, the milk being supplied in individual feeding bottles, which are returned the following day. An experienced nurse or a physician is in attendance at each station, and in general an admirable dispensary system has been arranged to supplement the work of the sanatorium, which, during the summer months, each year, cares for a number of children suffering from intestinal disorders. The possibilities of more searching preventive work through a dispensary system will be given a thorough test.

Pamphlet on Tuberculosis.

The State Board of Health recently gave out a prize for the best pamphlet shortly to be issued, written especially for the laity, and intended for distribution broadcast, in which consumption is described, its ravages clearly pointed out, and rules for its prevention and limitation of its spread detailed. The State Board of Health announces that it will make free examinations, too, of sputa in needy cases.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

BELFAST.

Cerebro-Spinal Meningitis.—There were 29 cases of this affection reported last week, as compared with 30 the week before; the total number up to date is 420. There were 16 deaths reported, bringing the number up to 295. There are 90 patients in the Purdysburn fever hospital, 43 of whom are suffering from cerebro-spinal meningitis. At the last meeting of the Public Health Committee some discussion took place as to the wisdom of allowing visitors into hospital, and Dr. Gardner Robb said that he believed nearly 1,500 persons had visited the hospital to see patients or remove the bodies of dead friends, and none of these visitors had received any harm from doing so. In one case in which it was supposed that a case of cerebro-spinal fever had arisen in this way, it was found that the supposition was not justified. He was confident the visitors ran no risk, but overalls were being provided, and would perhaps allay any alarm that might be felt.

The Health Commission.—The meetings of the Health Commission have been resumed in the past week, and some interesting evidence has been heard. One whole day was taken up by the assistant city surveyor, who gave many particulars about the houses in the poorer districts of the city, and the efforts that have been made to improve their sanitary condition. One fact is quite clear, that all the efforts of the civic authorities will be unsatisfactory in their results as long as the people generally have such exceedingly elementary ideas of cleanliness. For instance, where baths are provided in some of the newer working-class houses, it is common to find them in a filthy state, and used for anything except for personal ablutions. In one of the very worst streets, where the people seem to be in dire need, the agent stated that there were tradesmen earning good wages among them, and labourers earning 24s. a week, but that they "drank too much." The question of pig-keeping excited a good deal of interest. It appears that large numbers of pigs are kept in the poorer parts, and if the styes are more than fifteen feet from the living rooms, they are not objected to by the authorities. Dr. Henry O'Neill, who has been a member of the Public Health Committee for fourteen years, gave evidence as to his efforts to promote reform. His chief complaint was that when by-laws pressed hardly on anyone, that person would bring influence to bear on the Committee whose duty it was to see the law administered, and would get it relaxed to suit them. He gave several instances of this being done to allow building to proceed on sites which had at first been refused as unsuitable. Mr. P. J. Kelly, inspector of National schools, gave most interesting evidence as to the 194 city schools, in which the number of scholars exceeds those in the National schools of Dublin, Cork, Derry, Limerick and Waterford combined. The schoolrooms have generally been built to be used as lecture or meeting-rooms in the evenings, and often five or six teachers have to teach in the one room for want of proper accommodation. Only 24 of the schools are heated by hot water, and in the others the heating is often most inadequate, and in cold weather the windows are closed to keep in the heat. Forty per cent. of the schools had no playgrounds, and 20 per cent. only moderate ones. The witness considered the whole system in great need of revision.

Medical Benevolent Fund.—The annual meeting of the Belfast branch of the Royal Medical Benevolent Fund Society of Ireland was held in the Medical Institute, Belfast, on May 17th, Professor Lindsay presiding. Dr. Purdon, the hon. secretary and treasurer, read the annual report, which stated that the contributions amounted to £157, the local expenses were £10, and the balance was remitted to the central fund. Unfortunately, over 70 of the 200 medical men in Belfast contributed nothing. The report was moved by the President, seconded by Dr. R. W. Leslie, and passed. Dr. Victor Fielden was elected to succeed Dr. Purdon, who resigned his office, and was accorded the warmest thanks of the meeting for his many years of active and unselfish efforts on behalf of the fund.

LETTERS TO THE EDITOR.

THE MEDICAL DEFENCE UNION AND ITS WORK.

To the Editor of The Medical Press and Circular.

Sir,—The Union has to thank you for your report of its work. I must, however, ask to be allowed to correct one statement made in your editorial. You write that law costs are "a variable and controllable factor." I can only say that we wish this was so. It is impossible to estimate the costs in any legal action, and, as no legitimate expense can be spared by the Union in the defence of its members, we have to incur necessary risks. One case alone cost over £700, and in another the expenses will be even more than this amount; and yet not one single penny of such expense could have been avoided. Cheap law, like cheap medicine, is not an element which makes for success, and it is proverbial that law is a luxury but a luxury which at times becomes a necessity. No case is handed over to our solicitor which could possibly have been dealt with by the lay executive, and hundreds of pounds are saved each year by checking threatened litigation at the onset. There is one other statement which you make in your leaderette to which I must make a reply. You state that the holding of the annual meetings in the provinces is "hardly calculated to secure a proper control of the affairs of the society by members." I fail to understand this criticism. Our members are drawn from the provinces in a far larger proportion than from London, and it is only fair to give our members outside London a chance of attending annual meetings by holding these in centres nearer than London. In this we follow the example of the British Medical Association, and the value for recruiting purposes has been widely proved. There is a tendency amongst some to imagine that everything connected with the medical profession should be dealt with in London. It is true that the actual work is in the case of the Union accomplished here, but in order to give the provincial member an opportunity to attend the annual meetings, we have decided to select a centre each year outside London. I only wish we could extend our area to hold one meeting at least in Scotland, Ireland, and Wales, but am afraid this would not be convenient. If all our members belonged to London, it would be, of course, imperative to hold our general meeting here, but that not being the case, it is surely right and proper to allow our provincial members an opportunity of control and criticism.

I am, Sir, yours truly,
A. G. Bateman,
Gen. Sec.
4 Trafalgar Square, London, W.
May 17th, 1907.

LONDON HOSPITALS AND GENERAL PRACTITIONERS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your correspondent "R.L." takes the philosophical and experienced view that readers of your esteemed journal must have learned to associate with those initials. To my mind the teaching at most of our London hospitals is of an unequal and amateurish kind. The great teacher is born not made, but under present conditions any man who has the special intellectual faculty necessary to pass a high standard examination, and the necessary resolution and means to wade through the probation of a teaching hospital staff appointment, necessarily becomes at the same time a "teacher" (save the mark!) It is just as necessary for a man to learn how to teach as it is for a carpenter or a watch-maker to undergo an apprenticeship. I have seen something of all sorts of practice in all kinds of London hospitals. It is my deliberate opinion that all men on hospital medical staffs should be paid for their services to the hospital, and much more so for the time and labour expended on teaching students. Any capable man should command a liberal salary—as much, say, as the income of an average good benefice, or a county court judge, or a barrister in fair practice. As things go the teacher who gets fragmentary glimpses at disease in scattered consultations can hardly impart a view of disease in the broader continuity that will be required by the student in later life. This subject is well worth prolonged discussion in your columns, and I trust some others will come forward with their opinions.

I am, Sir, yours truly,
Maidenhead. GENERAL PRACTITIONER.

CHILDREN'S HOSPITALS AND MILK.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—With reference to the paragraph in last week's MEDICAL PRESS AND CIRCULAR, I beg to inform you that restrictions were imposed upon the milk contractors very similar to those recommended at the Conference held at this hospital, but that the object of the Conference was to insure the uniformity of these restrictions and unity in action.

I am, Sir, yours truly,
STEWART JOHNSON, Secretary.
The Hospital for Sick Children,
Great Ormond Street, London, W.C.,
May 18th, 1907.

OBITUARY.

WILLIAM T. GIRDLESTONE, M.R.C.S., L.S.A.

WE regret to record the death of Mr. William Theophilus Girdlestone, late of Rhyl, on May 11th, at his residence at Kensington, in his seventy-fifth year. The fourth son of the late Rev. Charles Girdlestone, vicar of Sedgley, Staffordshire, he was born in 1832, and received his professional education at St. Bartholomew's Hospital. He was admitted a member of the Royal College of Surgeons, England, in 1856, and a licentiate of the Society of Apothecaries in 1857, and long practised at Rhyl, where he was honorary surgeon to the Royal Alexandra Hospital and Convalescent Home. Mr. Girdlestone, who had retired from practice, was a magistrate for Flintshire.

ALEX. McLAGAN WEDDERBURN, M.D.Aber.

THE death will be regretted of Dr. McLagan Wedderburn, Forfar, lately Medical Officer of Health for the County of Forfar, who died on May 15th in Edinburgh, where he had gone for the benefit of his health. Dr. Wedderburn was partly educated in Aberdeen and Blair College, near Polmont, and afterwards studied at Aberdeen University, where he graduated. He went to Forfar about forty-five years ago as assistant to Dr. Steele, and became his partner in the following year. On December 16th, 1890, he was appointed Medical Officer of Health for the county, retiring from the post in May last year. He had attained his 67th year, and leaves a widow, five sons, and five daughters.

SPECIAL ARTICLE.

PROPOSED CHANGES IN THE BRITISH PHARMACOPŒIA.

WE are favoured with an advanced Report to the Pharmacopœia Committee of the General Medical Council on the changes in the next issue of the *British Pharmacopœia* that will be necessary to give effect to the International Agreement (1906).[a] (Adopted by the Committee of Reference in Pharmacy, March 4th, 1907.)

Aconiti Radix.—The restriction limiting the drug to roots that have been kept not longer than one year could be introduced by a statement to that effect, but no description could be framed that would exclude roots more than a year old. To be in strict accordance with the letter of the Agreement, the name should be altered to "Aconiti Tuber."

Aconiti Tinctura.—There would be no difficulty in preparing a tincture containing 0.05 grammes of total alkaloid in 100 grammes of tincture. The average alkaloidal strength of the present tincture would probably have to be ascertained in order that the dose might be adjusted accordingly.

(The Provisional Agreement of 1902 gave an alkaloidal strength of 0.025 per cent.)

Belladonnæ Folium.—The drug can easily be restricted to the dried leaves (*i.e.* not branches, flowers, &c.).

Belladonnæ Tinctura.—Tincture of Belladonna made from the leaf instead of the root would, of course, be totally different in appearance from the present tincture. A 10 per cent. tincture made from leaf of good quality would be approximately the same alkaloidal strength as at present. It should certainly be standardised to 0.05 per cent. of alkaloid (as at present).

Belladonnæ Extractum.—This would also differ in appearance from the extracts at present official. It should certainly be standardised, as the unstandardised extract has been found to vary in alkaloidal strength from 1.5 to 4.5 per cent. This variation would be very dangerous. The extract, standardised to 1.0 per cent. of alkaloid, might well take the place of both the present official extracts of Belladonna.

With regard to the other preparations of Belladonna, the liniment is probably best made from the root, and if the present standardised liquid extract of the root were retained, then the liniment, plaster, ointment, and suppository could all be made from it as at present, and thus comparatively little alteration would be necessary; otherwise a standardised liquid extract of the leaf would have to be introduced, from which the other preparations could be made. The liniment would in this case be very highly coloured and unpleasant to use. It will probably be necessary to have standardised liquid extracts of both leaf and root, from which the other preparations can be made.

The use of an extract containing, as it might, 4.5 per cent. of alkaloid in the place of the present green extract, which often contains less than 1 per cent., might be attended by very serious results.

Colchici Tinctura.—According to the Agreement this tincture is to be made in the proportion of 100 grammes of seed to 1,000 grammes of 70 per cent. alcohol (specific gravity 0.890). The most convenient method for British pharmacists would probably be to use 89 grammes of seed to 1,000 c.c. of menstruum, which would be the same proportion. The new tincture would be nearly half the strength of the present, and the dose might have to be correspondingly increased.

Digitalis Tinctura.—The tincture of the Agreement would be about three-fourths the strength of the present (1,000 : 730); the dose might have to be proportionately increased.

(a) **Treaty Series No. 10. International Agreement respecting the Unification of the Pharmacopœial Formulas for Potent Drugs. Signed at Brussels, November 29th, 1906. Presented to both Houses of Parliament by Command of His Majesty, March, 1907. His Majesty's Stationery Office. [Cd. 3392.] Price 1½d.**

Ipecacuanha.—The powder is to be prepared from the bark only of the root, and contain 2 per cent. of alkaloid. This can easily be done, and the powder will be about the same strength as the present.

Ipecacuanhæ Tinctura.—Prepared according to the Agreement, this should contain 0.2 gramme of alkaloid in every 100 grammes of tincture (assuming that the drug is exhausted). A standardised liquid extract similar to that at present official, but made (as it should be) without the aid of lime, might be used for making this tincture, which would then have the advantage of being standardised.

Hyoscyami Folium.—Only the leaf is to be used.

Hyoscyami Tinctura.—This would be approximately the same strength as at present, and no change would be necessary beyond the alteration of the quantity of leaf for every 100 c.c. of tincture.

Extractum Hyoscyami would be made in the same manner as Extractum Belladonnæ. It would be necessary to determine the relative average alkaloidal strengths of the old and new extracts, and adjust the dose according. In all probability an inconvenience and even danger, similar to that mentioned under Belladonna, will result in this case also.

Nux Vomica.—The standardisation of the seed to 2.5 per cent. of total alkaloid as required by the Agreement can easily be complied with, but the step is a very retrograde one, as the proportion of strychnine to brucine in the total alkaloid has been shown to vary from 1 : 1 to 1 : 1.8. Hence genuine seed passing the test of the Agreement may vary as much as from 1.0 to 1.4 in their toxicity. Moreover, standardisation to total alkaloid does not ensure the presence of any strychnine whatever. It seems essential that these seeds, or at least preparations of them, should be standardised in terms of strychnine.

Assuming that the Agreement considered that the proportion of strychnine present varied but little from one-half the total alkaloid, which, however, is not in accordance with the results of recent investigations, compliance with the spirit of the Agreement would be attained by standardising Nux Vomica to 1.25 per cent. of strychnine, instead of 2.5 per cent. of total alkaloid. It would in all probability be impossible to devise a means of standardising to 2.5 per cent. of total alkaloid, of which one-half should be strychnine. Compare *Reservation IV* of the Agreement, by which Great Britain reserves the right to make such modifications in detail as the progress of science may from time to time render necessary.

Nucis Vomicæ Tinctura.—Similar observations apply to the tincture. It might be standardised to 0.125 per cent. by weight of strychnine, instead of 0.25 per cent. of total alkaloid. As the tincture would then be approximately one-half the strength of the present, the dose might require adjustment.

Nucis Vomicæ Extractum.—It might be possible in exceptional instances to produce an extract with 8 per cent. of strychnine, but the average of good commercial seeds will yield a *dry* extract containing considerably less than that amount. Probably it will be practically impossible to produce an extract of the strength demanded by the Agreement. The natural standard for Nux Vomica extract is undoubtedly 5 per cent. of strychnine.

Opii Pulvis.—The temperature at which opium is dried for standardisation will require changing from 100° C. to 60° C.

Opii Tinctura.—This will be one-sixth stronger than the present tincture; the dose may require adjustment accordingly.

Opii et Ipecacuanhæ Pulvis Compositus.—This name will have to replace, or be given as a synonym of, Pulvis Ipecacuanhæ Comps

Strophanthi Tinctura.—The new tincture will be nearly four times as strong as the old; the dose may have to be diminished to about 1 to 5 minims, which would be inconveniently small, and the great difference in the dosage might produce very untoward results.

Ergotæ Extractum.—The new extract will be a different preparation from the old. Its suitability for making the Hypodermic Injection will have to be ascertained.

Ergotæ Extractum Liquidum.—Neither the menstruum nor the mode of procedure is specified, so that apparently no change will be necessary.

Sodii Arsenas.—The crystalline salt would have to be described. The Agreement does not refer to Liquor Sodii Arsenatis, so that this preparation could be left unaltered.

Liquor Arsenicalis.—The present strength would require slight alteration to bring it to 1 per cent. by weight.

Liquor Arsenici Hydrochloricus would in this case probably be brought into line with Liquor Arsenicalis.

Ferri Iodidi Syrupus.—The present strength would be considerably diminished.

Cantharidis Tinctura.—The strength of the new tincture would be 1 in 10, instead of 1 in 66.7; the dose might require adjustment.

It is doubtful whether 1,000 grammes of 70 per cent. alcohol would retain in solution the cantharidin extracted from 100 grammes of cantharides, which might easily exceed 0.8 gramme; this point should be ascertained by experiment.

Iodi Tinctura.—The tincture of the Agreement would contain 10 in 100 (by weight); the present tincture contains 10 in 333.6. Alcohol of 95 per cent. is not official. The dose (if a dose were given) would have to be diminished to about one-third. Apart from this inconvenience, much trouble may result from the large increase in strength of a preparation so widely used for external application.

Lobeliæ Tincture is not at present official. Tinctura Lobeliæ Ætherea is nearly twice as strong.

Hydrargyri Unguentum.—A considerable reduction in strength would have to be made (by rather more than one-third). Account would have to be taken of this in those preparations into which Unguentum Hydrargyri enters.

Vinum Antimoniale.—An unimportant alteration in strength would take place owing to the wine being weighed instead of measured.

REVIEWS OF BOOKS.

VARIATION, HEREDITY, AND EVOLUTION. (a)

THE cares of this world are apt so exclusively to engage the attention of the medical man in practice that he perforce loses touch with the recent developments of the pure sciences, although it is eventually on these that the art of medicine is based, and on their successful pursuit that progress in the science of medicine depends. In few subjects of late years has such extraordinary activity taken place as in the study of variation and heredity, and though we still see through a glass pretty darkly, we have already glimpses which promise early visions of things undreamed of ten years ago. Indeed, it is hardly too much to say that the salvation of mankind depends on the scientific comprehension of the factors that produce variation, of the use that can be made of these with regard to heredity, and of the employment of them for the attainment of physical and moral advance. In a word, the future of the race lies rather in the shaping of heredity than in the production of an environment, though all our modern humanitarian, sanitarian, and democratic aspirations take only the latter into account. It is true that till lately "Genetics"—as the science is now termed—has attracted little public notice, and that so far as it is known it is misunderstood; but though it is not yet able to take its place in the hierarchy of the practically useful sciences, the day is fast coming when it will. To what, then, is this new over-enthusiasm due to? Theories of heredity are at least as old as Aristotle, and for more than half-a-century the battle of the transmission of acquired characters has been in full force, the champions on both sides equally distinguished for learning and sagacity. Of course, the new school of "Genetics" has not been born of a single circumstance, but there is no denying that the re-discovery of Mendel's law has given the whole question a certainty, an interest, and a prestige which have attracted many inquirers. As was the case with physiology in the seventies, the school where there is most of life and enthusiasm is at Cambridge, in which, under the inspiring influence of Mr. Bateson, a band of workers are learning and teaching. The book that lies before us is from the pen of one of the latter, and its object is to place before people in popular language and in simple form, the present position and acquirements of the science, and its prospects for the future. Mr. Lock has certainly produced a most interesting and suggestive volume, but how far it is likely to attract non-scientific students we should hesitate to express an opinion. To take the chapter on Biometry, for example, we should fancy few not in extreme earnest would strive to master the plan of the mathematical curve, which may seem simple enough to the mathematician under such a formula as "$Y = E - X^2$," or the theory of the pure line and its possible developments with regard to a mixed population. Nor is the theory of that "important kind of discontinuous variation" known as homœsis, nor even Mendel's law itself, that "the gametes of a heterozygote bear the pure parental allelomorphs completely separated from one another, and the numerical distribution of the separate allelomorphs in the gametes is such that all possible combinations of them are present in equal numbers," the sort of light reading that can be indulged in at disjointed intervals. But the whole subject is one of immense importance, and medical men who want to keep abreast of modern knowledge have no alternative but to give it close and strenuous application. For "genetics" in the course of this generation is likely to transmute many of our most cherished ideals.

INDEX CATALOGUE OF THE SURGEON-GENERAL'S LIBRARY, U.S.

We have received the eleventh volume of the second series of the Index Catalogue of the Library of the Surgeon-General's Office, United States Army. It extends from Mo. to Nystrom, and consists of 858 double-columned pages containing 8,023 author's names, 5,034 book titles, and 24,211 journal articles. The library now contains 155,292 bound volumes and 271,851 pamphlets. Including this, the eleventh volume of the second series, the Index-Catalogue contains 256,008 book titles and 846,271 pamphlet titles. Members of the medical profession engaged in literary work know how valuable this great index is, especially those engaged in historical research. Its pages reflect the opinions of each school of medicine and every fashion on therapeutics.

In producing this great work, and in giving it as a free gift to our public libraries and medical journals, the U.S.A. Government has made medicine their debtor for all time.

McMURRICH ON THE DEVELOPMENT OF THE HUMAN BODY. (*a*)

A knowledge of the main facts of embryological science is not only interesting to the pure physiologist, for it is, indeed, by the aid of the study of the development of the various organs and tissues of the body that new light is frequently shed upon morbid processes in general. The present volume before us, which has reached a second edition in a comparatively short time, has incorporated within some of the more recent work of Professor Hertwig, which should render it of greater value than ever to students and teachers of embryology. The book is divided into two main portions, the first dealing with the development of the germinal layers and the fœtal membranes, while the second treats with that of each system of the body in detail. The style is not too heavy, and there are nearly three hundred illustrations, many of which are from photographs. Recognising the important fact that "development does not cease with birth," the author has added a chapter on "Post-Natal Development." A bibliography is also added after each chapter, and there is a copious index. Dr. McMurrich is to be congratulated upon a thoroughly useful text-book.

PRACTICAL SANITATION (*a*).

This volume deals with the subjects that are usually included under the comprehensive title of "Sanitation," in a manner that is satisfactory on the whole, but there are several points on which the book is not up to date, and others where the accuracy might be questioned. The dilution for use of "Cyllin," "Chinosol," and formalin is given as 1 in 100 in each case, disregarding the fact of the very different efficiencies of the three disinfectants. In dealing with the subject of tuberculosis in a book recently published, one would naturally expect to find a reference to the first Interim Report of the Tuberculosis Commission (the book was published before the second Interim Report was issued), but instead we find the Commission referred to as being "recently appointed," and the subject is thus only brought up to the position of 1901. One might also reasonably expect a reference to the Glover Lyon method of ventilation, which so far as we are aware is the most satisfactory. These small omissions detract from what otherwise would be an admirable volume, and which even as it stands is one that can be recommended to those desiring to gain an acquaintance with sanitation. The fact that twelve editions have been issued in fourteen years is proof of its popularity, and the present edition is a great improvement on the previous one, as the chapter on "Sewage Disposal" and the Appendix on "Sanitary Law" have been revised and re-written.

THE STUDY OF CHILDREN'S DISEASES. (*b*)

Judging by this volume, the sixth year of the society's existence has been one characterised by useful work. The articles and cases are all of interest, and in many instances of great permanent value. In the opening pages there are records by Drs. Whiphoun, Parkinson, and Cautley of a series of cases of splenomegaly, and these are followed by a highly-instructive discussion on this obscure disease. Congenital hypertrophy of the pylorus continues to excite much attention among physicians and surgeons to children's hospitals, and the best method of treating it is by no means yet settled. It is not surprising, therefore, that several papers on this subject appear in the volume; they are contributed by Drs. Carpenter and Cautley. One of the chief items is a series of papers on serous and purulent pleural effusion, by Drs. Emanuel, Dudgeon, Bythell, Carpenter, Sutherland, Hobhouse, and Lockhart Mummery, in which the important subject is exhaustively treated of from various points of view. The Reports are also a mine of wealth in short notes of rare cases; they are becoming year by year more valuable in this respect, and one turns to them, seldom in vain, when anxious to find records of out-of-the-way diseases. This year we may note, among others, Dr. Guthrie's notes on lipomatosis and fragilitas osseum, Dr. Hay's case of achondroplasia, Dr. Lett on precocious development, and Dr. McCaw's case of chlosoma. In the last, unfortunately, there was no autopsy. Enough has been said to show the value of these Reports; and we have only again to congratulate the Editor on the appearance of the annual volume.

Weekly Summary of Medical Literature, English and Foreign.

Specially compiled for The Medical Press and Circular.

RECENT MEDICAL LITERATURE.

Protection of Rheumatic Children.—Hawthorne (*The Brit. Journ. of Children's Diseases*, March, 1907) discusses the possibility of the prevention of cardiac disease in children suffering from rheumatism, He points out that it is the non-arthritic forms of rheumatism which are most frequently followed by cardiac complications, but that it is this very form of rheumatism which is so common in children. In the case of adults, where the disease usually shows itself as a painful polyarthritis, the patient is driven by the pain to rest in bed, but the rheumatic child, even during an active phrase of the disease, suffers little or no pain, and thus the circumstances, permit him to escape the rest which an acute polyarthritis invariably demands. The public are not yet sufficiently aware of the dangers of this so-called ambulatory rheumatism in children, and so the necessary rest is not insisted on. The remedy for this lies in the education of parents, and Dr. Hawthorne concludes that "the discovery of signs or evidences of rheumatic disease in any family ought to be the occasion, as an imperative professional duty, to convey to the parents information and warning of the special risks which even the apparently slight illnesses of their children may involve, and of the importance of complete rest as a means of avoiding these risks." K.

Pericolic Inflammation.—Newton (*The Med. Chronicle*, April, 1907) discusses the varieties of this condition, first described in 1890 by Windscheid. Pericolitis may occur anywhere along the course of the large intestine, but by far the commonest site is in connection with the descending colon, especially low down near the commencement of the sigmoid flexure. Many explanations have been offered of the pathology of the condition, but none can as yet be said to be completely satisfactory. All are agreed that in the majority of cases constipation plays a very prominent part, though there are some instances in which there was no previous history of this trouble. The hypothesis which seems to explain best the condition and which is best supported by the available *post-mortem* data, is as follows:—In a certain number of subjects of chronic constipation are found after death to have sacculi of varying sizes in the walls of the large intestine. It is suggested that in chronic constipation the action of the accumulated fæcal material on these small protusions of mucous membrane causes them to enlarge and become definite sacculi comparable to a small appendix. In these sacculi hard fæces accumulate, and by irritation set up an inflammation of the mucous membrane, which allows the bacteria of the intestine to invade the peritoneal covering of the colon with the resulting pericolitis. Perforation of the intestine by small foreign bodies ingested with the food, injuries received from without and finally leakage from typhoidal, stercoral and other ulcers have been known to cause the condition. As regards treatment many cases may be cured by rest in bed and relief of the constipation by enemas. The recumbent position is of considerable importance, as it favours the passage onwards of the contents of the ascending colon. In some cases, however, it is necessary to open the abdomen and divide the adhesions, being very careful afterwards to keep the bowels acting freely, for if constipation occur again the adhesions are likely to reform. In some intractible cases anastomosis of the ileum with the sigmoid flexure has been advised. In any case of chronic constipation in which the constipation is not relieved by enemas, rest or other methods, some operation appears to be necessary. K.

Treatment of Chronic Morphinism.—Dixon (*The Practitioner*, May, 1907) is decidedly opposed to the sudden withdrawal of the drug in these cases, except where very small doses have been taken. With patients in the habit of taking large doses he advocates the diminishing of the morphine in the first twenty-four hours to half the usual quantity taken, and then the gradual reduction during the next eight or ten days to a vanishing point. In Dixon's experience it has been the withdrawal of the last two or three grains that has proved especially difficult, and he believes with Dr. Jennings that at this stage the substitution of opium per rectum for morphine injections is often useful. The use of hyoscine has many advocates, but the writer of the paper does not give any details of the treatment by it. The after-treatment of these patients is of great importance, and the general opinion is that they should not be permitted to return home till after the lapse of about a year.

K.

Progress of Anti-Typhoid Inoculation in the Army.—Leishmann (*R.A.M.C. Journ.*, May, 1907), reviews the history and progress of this method of prophylaxis, which has been recently again introduced into the army as a voluntary measure. The experiences during the Boer War were so unsatisfactory and so much diversity of opinion existed as to the merits of the method that it was for a time abandoned. The chief stumbling block was the danger connected with the negative phase. The method of inoculation was then abandoned, and a committee was appointed by the Army Council to re-investigate the whole matter. This committee is still in existence, and it is upon its recommendation that the typhoid inoculation has again been adopted. At present two inoculations are given with an interval of ten days between the first and second, and the dosage for these inoculations has been fixed at 500 million bacteria for the first and 1,000 million for the second inoculation. A very considerable amount of work has also been done with regard to the preparation and standardisation of the vaccine, but in connection with this much yet remains to be done. The question as to whether a virulent or non-virulent strain of typhoid bacilli should be used for the preparation of the vaccine is not yet definitely settled, and it has not been found possible up to the present to do away entirely with the local reaction. The results so far are very encouraging, and Leishman looks forward with confidence to the method being firmly established within a short period. K.

Irrigation Treatment of Gonorrhœa.—Purdy (*The Scottish Med. and Surg. Journ.*, May, 1907) relates the results of some experimental and clinical work on this method of treatment. From experiments on the cadaver he has found that with an ordinary 4 drachm syringe it was not possible to inject fluid beyond the membranous urethra, but with a douche an elevation of three feet caused the fluid to pass into the bladder. In the living subject he found it necessary to use an elevation of at least 5½ feet in order that intra-vesical irrigation should be effective. In practice Purdy uses a double channel nozzle consisting of two tubes concentrically placed so as to allow the fluid to flow through the inner and return by an outlet placed at an obtuse angle in the outer. With such a nozzle attached to the tube of an ordinary douche-can elevated three feet, the urethra is washed out, using warm boracic lotion, followed by a solution of 1 in 5,000 of potassium permanganate. The patient is then directed to inject himself three times a day with a 10 per cent. solution of argyrol, which he retains in the urethra for a period of from five to seven minutes. The irrigation is repeated every second day until all obvious discharge has ceased, when an injection of sulphate of zinc, one grain to the ounce, is ordered for a few days. In this way Purdy has cured an ordinary gonorrhœal anterior urethritis in about a week. With posterior urethritis the treatment may have to be prolonged over a much longer period, and the douche-can must be raised to a height of about five feet. K

Treatment of Disease by Passive Hyperæmia.—Dr. Schmieder contributes to the current number of *Folia Therapeutica* (April, 1907, p. 48) an account of Bier's treatment of various morbid conditions by the induction of a condition of passive hyperæmia in the diseased part. Three principal methods are employed to secure this result, viz., (1) hyperæmia by means of a compression bandage placed above the diseased part and so adjusted to prevent venous return without completely obstructing arterial flow; (2) by suction apparatus, represented in its simplest form by cupping glasses. This method is particularly suitable for circumscribed abscesses, boils, and sinuses; (3) by hot-air chambers, which are specially applicable to chronic joint diseases. The writer points out that the treatment was chiefly used for tuberculosis up to the year 1905, and states that since that time it has been applied with success to almost every variety of localised suppurative process. M.

Toxins of Tubercle Bacilli Present in Individuals Suffering from Tuberculosis.—Rappin has examined the milk obtained from eleven women in different stages of tuberculosis (*La Province Med.*, January 12th, 1907), and has shown the presence of tuberculous toxins within it. Having obtained the milk under careful aseptic precautions and having boiled it for ten minutes, he injected some into tubercular guinea-pigs, keeping under control healthy animals under observation. He found that after three or four hours, there was produced in the diseased animals a reaction similar to what is produced by the injection of small doses of tuberculin. The author regards this demonstration as most important, and points out that it may help to explain the apparent hereditary character of the disease. At first sight it might appear that the continuous injection of small doses of tuberculin would gradually cause immunisation, but all the known facts of anti-tubercular sero-therapy are opposed to this view, and serve to show that the continuous injection of the toxins rather tends to lower resistance than otherwise. Their presence in milk is an additional argument against phthisical patients nursing their children. M.

The Communicability of Cerebro-spinal Meningitis..—Bolduan and Goodwin make a preliminary report of the work which they have been doing for the Special Commission on Cerebro-spinal Meningitis in New York (*Indian Med. Record*, March 28th, 1907, page 1). The work was principally directed towards the discovery of the probable source of contagion, and included an investigation of the bacteriology of the disease. They formulate the following conclusions: (1) The disease hitherto always occurred in epidemics, more or less linked by intervening sporadic cases. (2) The epidemic form always, and the sporadic form usually, is associated with the presence of the meningococcus of Weichseltaum. (3) During the first week of the disease, the meningo-coccus is present in the nasal mucus in fully half of the cases; later in the disease it is found in a small fraction of the cases. It also occurs in the nasal mucus of about 10 per cent. of persons who are in close contact with cases of cerebro-spinal meningitis. (4) The disease seems distinctly communicable in the sense that the organism is transmitted from the nasal secretion of one person to another, but the transmission of the organism is not synonymous with transmission of the disease. (5) The organism is rapidly killed by drying and by sunlight, facts which make dust infection improbable. (6) There is no evidence to show that the disease is carried by vermin or by insects. M.

Reflexes in Cases of Complete Transverse Section of the Spinal Cord.—According to Lapinsky (*Archiv. fur Psych. und Nervenheilk*, Bd. 42, Heft 2), the disappearance of the reflexes in paralysed parts after complete division of the spinal cord, should not be attributed to a removal of the reflex controlling properties of the cerebellum, since the existence of such properties has never yet been proved. In many cases of flabby paralysis, the cause is rather to be sought in some organic change in the reflex arc. The cause of such a change may be effusion of blood into, or œdema of the grey matter of the spinal cord; a possibly swelling up of the myelin in the degenerating tract of the cord. Furthermore, an increase of the cerebro-spinal fluid may play a part, by causing compression and interfering with the nourishment of the cord. M.

Hysterical Insanity.—Raecke (*Berlin Klin. Woch.*, March, 1907) describes several forms of hysterical psychosis which are important because they are easily mistaken for incurable mental or nervous disease, such as dementia precox and apoplexy. Three types can be distinguished: (1) The excited, stuporous form in which outbreaks of mania alternate with periods of retardation; delirium and attacks of somnambulism may occur. (2) The depressive form, with attacks of anxiety, stupor, confusion, and melancholia. (3) The paranoid type with systematic delusions of persecution. The diagnosis is made partly on the previous history, partly on the general hysterical behaviour of the patient, while the hysterical stigmata are often absent. The prognosis is always favourable as to the eventual outcome, but the course is often tedious. The treatment is that of hysteria in general. D.

The Diagnosis of Infantile Scurvy.—Von Starck (*Mun. Med. Woch.*, March, 1907) considers the following symptoms of infantile scurvy as most important. (1) Increasing anæmia, (2) hæmorrhagic swelling of the gums, (3) pain on motion, (4) periosteal swellings, (5) hæmaturia, and (6) exophthalmus and hæmorrhagic swelling of the eyelids. It should be noted, however, that anæmia is not necessarily present in the early stages. The swelling of the gums may be slight, but the characteristic purple discolouration is almost always present. X-ray examination may be important showing a dark transverse shadow at the end of the diaphysis and at times also periosteal swellings due to hæmorrhage. The prompt response to treatment with fruit juices and raw milk may be of diagnostic aid in obscure cases. D.

The Value of the Benzidin Test for the Demonstration of Minute Hæmorrhages.—Schlesinger and Holst (*Mun. Med. Woch.*, March, 1907) report results with the benzidin test for blood in the fæces and urine. As performed by them, the test is never positive in persons on a meat free diet, unless there is blood present. A piece of fæces the size of a pea is used for the test; the reagent consists of a mixture of ½ cm. of a freshly prepared solution of benzidin in glacial acetic acid, with 3 cc. of a 3 per cent. solution of hydrogen peroxide. The bit of fæces is stirred up in one-fifth of a test tube of water, the reagent is added, and the whole shaken. If blood is present a handsome blue colour appears, or if the amount is small a clear green. When urine is to be tested, it should be treated first with a small volume of glacial acetic acid and extracted with ether. The ether extract is cleared with a few drops of absolute alcohol, removed with a pipette, and added to the benzidin reagent. The test is especially valuable in hæmoglobinuria, where the microscopic examination for microcytes is negative. D

Owing to an epidemic of measles and whooping-cough, five schools, attended by nearly 2,000 children, have been closed at Finchley for three weeks.

Medical News in Brief.

The German Hospital.

The 62nd anniversary festival dinner in aid of the funds of the German Hospital, Dalston, was held on May 11th at the Hotel Métropole, Baron von Stumm, the German Chargé d'Affaires, presided, and the company included Prince William von Stolberg-Wernigerode, Herr A. von Goldschmidt-Rothschild, Captain Ostertag, Prince Emil zu Fürstenberg, Consul-General H. S. J. Maas, Consul-General Daniel Danielson, Sir Julius Wernher, Mr. Alexander Siemens, and Mr. W. F. Cochrane, secretary. The chairman, in proposing "The German Hospital, coupled with the Duke of Connaught, the president," said the hospital contained 130 beds, which were, as a rule, always occupied; indeed, it frequently happened that patients had to be refused admission for want of room. The benefits of the institution were not confined to Germans. It was largely used by English patients living in the district in which it was situated, and all cases of accidents, no matter what the nationality of the injured persons might be, were at once admitted and treated with the utmost care. Last year 1,824 in-patients were treated, an increase of 65 over the previous year. Of the total number 216 were cases of accident, nearly all English. During the same period the number of new out-patients was 27,072, and the attendances 67,580. To maintain the hospital about £11,000 a year was required, and last year, but for some legacies, there would have been a deficiency of £350. The cost per occupied bed was the lowest of any hospital of the same size in London. Additional accommodation was urgently needed. Alluding to the announcement by the chairman of last year's festival that one or two friends intended to present the hospital with a new convalescent home at Hitchin, he said the donors, Mr. Fritz König and Mr. Hans König, had accepted plans for a handsome building to contain about 50 beds, and building operations would begin in a few weeks. Other toasts followed, that of "The Chairman" being proposed by Sir Julius Wernher. Donations and subscriptions were announced amounting to £3,758, including £200 from the German Emperor and £500 from the Emperor Francis Joseph.

Vivisection Commission.

Another volume of evidence taken before the Royal Commission on Vivisection has been issued. It contains statements made and presented by Mr. W. H. Power, C.B., principal medical officer to the Local Government Board, Dr. A. R. Cushny, professor of pharmacology and materia medica, University College, London; Lord Rayleigh, president of the Royal Society; Sir Douglas Powell, President of the Royal College of Physicians; Dr. F. Taylor, senior physician to Guy's Hospital, and also those by Miss Arabella Kenealy, L.R.C.P. (Dublin) and Mr. J. W. Graham, principal of Dalton Hall, Victoria University, Manchester, represented the Parliamentary Association for the Abolition of Vivisection.

After Care of Surgical Cases.

Alderman Sir Walter Vaughan Morgan presided at a meeting held on May 8th at the Mansion House in furtherance of the movement for establishing a "home of recovery" for surgical patients who when discharged from the London hospitals as convalescent require a further period of surgical care. To the committee which has been formed with this object in view Charing Cross, Guy's, University College, Middlesex, London, King's College, and St. Thomas's Hospitals have elected representatives, and it is proposed to erect and endow a home of recovery in which, on the recommendation of these general hospitals, the surgical treatment of convalescent persons can be effectively carried on. The home has been incorporated, and the President is her Royal Highness Louise Duchess of Argyll. Those present included the Earl of Lytton (chairman of the committee), the Countess of Lytton, Sir Richard B. Martin (hon. treasurer), Sir Alfred Fripp, the Archdeacon of London, the Archdeacon of Westminster, the Rev. F. Whyley (hon. secretary), Mr. W. J. Lancaster (assistant secretary).

Sir Walter Vaughan Morgan pointed out that though many of the hospitals possessed convalescent homes these were unable to admit patients unless they were actually convalescent. There was, therefore, plenty of room for the home of recovery. It would be an immense relief to the hospitals to make use of it, because not only would patients recover much more quickly than in London, but their removal to the home would make room for others who were waiting to come in for the purpose of undergoing surgical treatment. The committee had wisely decided not to start the home of recovery until they could see their way to building a suitable home and to keep it going. For this an appeal for £30,000 was being made.

Mr. Mayo Robson moved a resolution approving the objects of the home of recovery, as described in its trust deed, and expressing the hope that the committee would meet with adequate support in their efforts to alleviate much unnecessary suffering in cases which are unavoidably discharged from London hospitals in order to make room for more urgent cases awaiting admission. Sir Alfred Fripp seconded, Archdeacon Wilberforce and the Hon. Mrs. Campion supported, and the resolution was unanimously carried.

Royal College of Surgeons of Edinburgh.

The following gentlemen, having passed the requisite examinations, were, at a meeting of the College, held on 16th inst., admitted ordinary Fellows:—A. G. Bate, M.B., Ch.B.; J. H. M. Bell, M.B., Ch.B.; T. W. Eden, M.D., F.R.C.P.Lond.; W. Hume, M.B., Ch.B.; B. Ingram, L.R.C.S.E.; E. C. Lomas, D.S.O., M.B., M.R.C.S.Eng.; F. W. Lundie, M.B., Ch.B.; E. G. E. O'Leary, M.R.C.S.Eng., L.R.C.P. Lond.; W. H. Parkes, M.B., C.M.; A. M. Pollock, M.B., Ch.B.; C. H. Thomas, M.D., L.R.C.S.E.; R. S. Roper, M.R.C.S.Eng., L.R.C.P.Lond.; C. R. Whittaker, L.R.C.S.E., and J. C. Wilson, M.D., D.P.H. The medal and set of books presented to the College by Colonel William Lorimer Bathgate, in memory of his late father, William McPhune Bathgate, F.R.C.S.E., Lecturer on Materia Medica in the Extra-Academical School, was awarded after the usual Winter Session competitive written examination in Materia Medica, etc., to Miss Alice E. M. Babington, B.A., Greenfort, Fahan, Co. Donegal.

Soot and Cancer.

A more or less important contribution to the study of the mysteries of cancer has been made by the report of the departmental committee on compensation for industrial diseases. It is mentioned in this official document that the mortality from cancer among chimney-sweeps is twice that among ordinary males following an occupation. During the three years 1900-1-2 the number of chimney-sweeps who died of cancer was 133, as against 63 among occupied males of the same ages. It seems to follow, therefore, that soot has the quality of setting up an irritation of the skin liable to develop into cancer, but before holding soot altogether responsible it might be safer to examine a little more closely the conditions in which chimney-sweeps perform their work. It appears, at any rate, to be fairly established that the trade of cleaning chimneys involves more risks than had hitherto been supposed.

Royal Army Medical College.

The office of the Commandant of the Royal Army Medical College from No. 68, Victoria Street, Westminster, and the Laboratory from the Examination Hall, on the Thames Embankment, have been removed to the new College, in Atterbury Street, Millbank.

Queen's University, Belfast.

Sir Donald Currie has offered £10,000 towards a new recreation ground for the Queen's University, Belfast, for which a grand bazaar is to be held at the end of the month. Amongst the stallholders will be the Marchioness of Dufferin, the Countess of Shaftesbury, and the Countess of Annesley.

NOTICES TO CORRESPONDENTS, &c.

Correspondents requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Reprints.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

Tropics.—The summer session of the London School of Tropical Medicine began on the first of this month, but it may not be too late if you apply at once. There is a hostel attached to the school, where you can obtain board and residence on reasonable terms, and if you have only four months of your leave to run, you had better write to the secretary without delay.

J. B. Foster (Melbourne).—The question had better be addressed to the Registrar of the Royal College of Physicians, Pall Mall East, London. We have no knowledge of anything of the kind having arisen before.

Pensator (London).—We shall be glad to deal with the matter editorially on receipt of the necessary papers.

S. B. J.—We cannot open our columns to the discussion of a subject which is more a personal one than one of public interest.

House Surgeon.—The Committee could be approached and asked to allow a personal explanation to be given.

F. W. E.—The fee of £2 2s. in each case for each medical man is, we consider, the correct fee to name, and is one which may legally be paid by the Coroner. There is, however, no fee named in the Act, so far as we are aware, save a maximum fee, and below that maximum the amount paid is left to the discretion of the Coroner.

F.R.C.S.—Keratoplasty, or corneal grafting is not a new method of treating leucomata. It was suggested as long ago as 1824, by Reisinger.

Meetings of the Societies, Lectures, &c.

Wednesday, May 22nd.

Medical Graduates' College and Polyclinic (22 Chenies Street, W.C.).—4 p.m.: Mr. P. Paton: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Dr. H. French: The Vaccine Treatment of Acne and Some Points in the Treatment of Some other Common Maladies.

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—Cliniques:—2.30 p.m.: Skin (Dr. Meachen), Eye (Mr. Brooks), Medical Out-patient (Dr. Whipham).

Thursday, May 23rd.

Medical Graduates' College and Polyclinic (22 Chenies Street, W.C.).—4 p.m.: Mr. Hutchinson: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Dr. A. P. Beddard: Diabetes.

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Gynæcological Operations (Dr. Giles). Cliniques:—Medical Out-patient (Dr. Whiting), Surgical Out-patient (Mr. Carson). 3 p.m.: Medical In-patient (Dr. Chappel) 4.30 p.m.: Special Demonstration of Skin Cases (Dr. G. N. Meachen).

Hospital for Sick Children (Great Ormond Street, W.C.).—4 p.m.: Lecture:—Mr. Parsons: Convergent Squint.

Friday, May 24th.

Medical Graduates' College and Polyclinic (22 Chenies Street, W.C.—4 p.m.: Mr. E. Clarke: Clinique (Eye).

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—9.30 a.m.: Clinique: Surgical Out-patient (Mr. H. Evans). 2.30 p.m.: Surgical Operations (Mr. Edmunds). Cliniques:—Medical Out-patient (Dr. Auld), Eye (Mr. Brooks). 3 p.m.: Medical In-patient (Dr. Leslie).

Clinical Society of London (20 Hanover Square, W.).—Papers:—Dr. F. de Havilland Hall; Two Cases of Prolonged Pyrexia.—Dr. Gossage: A Case of Partial Heart Block.—Dr. F. W. Price: Foreign Bodies in the Bronchi. 9.30 p.m: Annual General Meeting.

British Electrotherapeutic Society (11 Chandos Street, Cavendish Square, W.).—8 p.m.: Council, 8.30 p.m.: Dr. Doumer (Lille): The Fundamental Principles of Electrotherapy. An Extraordinary General Meeting will be held for the purpose of winding up the Affairs of the Society.

Saturday, May 25th.

Ophthalmological Society of the United Kingdom (University of Edinburgh).—9.30 a.m.: Card of Specimens and Cases will be shown. 10 a.m.: Papers will be read and Demonstrations given.

Monday, May 27th.

Odontological Society of Great Britain (20, Hanover Square, W.).—8 p.m.: Mr. W. Sampson Handley, M.D., M.S., F.R.C.S.: "Lymphoid Degeneration of Salivary Glands." Mr. J. H. Badcock, L.R.C., M.R.C.S., L.D.S. Eng.: "Interim Notes on Orthodontia."

Vacancies.

Joint Counties Lunatic Asylum, Carmarthen.—Assistant Medical Officer. Salary £200 per annum, with board, lodging, washing and attendance. Applications immediately to W. Morgan Griffiths (Solicitor), Clerk to the Visitors, Carmarthen.

Joint Counties Lunatic Asylum, Carmarthen.—Medical superintendent. Salary £450 per annum, with unfurnished house, garden produce, fire, light, and washing. Applications immediately to W. Morgan Griffiths (Solicitor), Clerk to the Visitors, Carmarthen.

Royal Albert Edward Infirmary, Wigan.—Junior House Surgeon. Salary £100 per annum, with apartments, washing, and rations. Applications to Will. Taberner, General Superintendent and Secretary.

Oldham Union.—Resident Medical Officer. Salary £120 per annum, with furnished residence, coal, gas, rations, washing and attendance. Applications to Horace A. Quarmby, Clerk to the Guardians, Union Clerk's Office, Oldham.

Liverpool Hospital for Consumption and Diseases of the Chest.—Stipendiary Medical Officer and Assistant Pathologist. Salary £150 per annum. Applications to Alfred Shawfield, Secretary, 77a Lord Street, Liverpool.

Walsall and District Hospital.—Senior House Surgeon. Salary £100 per annum, with board, residence, and washing. Applications to E. J. Brookes, Chairman.

Bridgnorth and South Shropshire Infirmary.—House Surgeon. Salary £100 per annum, with board and lodgings in the Infirmary. Applications to the Hon. Secretary, the Infirmary, Bridgnorth.

Staffordshire General Infirmary, Stafford.—House Surgeon. Salary £100 per annum, with board, lodging, and washing. Applications to Richard Battle, Secretary, 7 Meyrick Road, Stafford.

Rochdale Infirmary.—House Surgeon. Salary £100 per annum, with board, residence, and laundry. Applications to Henry Booth, Secretary, Infirmary Office, 58a Yorkshire Street, Rochdale.

Newcastle-on-Tyne Dispensary.—Visiting Medical Assistant. Salary £160 per annum. Applications to the Honorary Secretary, Joseph Carr, Chartered Accountant, 26 Mosley Street, Newcastle-on-Tyne.

West Bromwich District Hospital.—Senior House Surgeon. Salary £110 per annum, with board, residence, and washing. Applications to T. Foley Bache, Esq., Churchill House, West Bromwich.

The Hospital for Sick Children, Great Ormond Street, London, W.C.—House Surgeon. Salary for six months £20, washing allowance £2 10s., with board and residence in the Hospital. Applications to Stewart Johnson, Secretary. (See advt.)

Alnwick Infirmary.—House Surgeon. Salary £140 per annum, with furnished apartments, attendance, coals, and gas. Applications to Wm. T. Hindmarsh, Honorary Secretary of the Alnwick Infirmary, 26 Bongate Without, Alnwick.

Bradford Royal Infirmary.—House Surgeon. Salary £100 per annum, with board and residence. Applications to John J. Barron, Secretary.

London County Asylums, Bexley, Kent, and Claybury, Woodford Bridge.—Junior Assistant Medical Officer. Salary £150 a year, with board, furnished apartments, and washing. Applications to H. F. Keene, Clerk of the Asylums Committee, Asylums Committee Office, 6 Waterloo Place, S.W.

Appointments.

Carrol, Denis J., L.R.C.P. and S. Irel., Medical Officer to the Clonmel Dispensary, Co. Tipperary.

Corbett, William Edward Manderson, L.R.C.P. and S. Irel., Medical Officer to the Stonehouse Branch of the Provident Dispensary in connexion with the Royal Albert Hospital, Devonport.

Croudace, J. H., L.R.C.P. and S.Edin., Medical Officer to the Stafford Workhouse.

Marson, F. H., M.D. Durh., Medical Officer and Public Vaccinator for Stafford District.

Paton, Leslie, B.A., M.B., B.C. Cantab., F.R.C.S., Assistant Ophthalmic Surgeon to the National Hospital for the Paralysed and Epileptic, Queen's Square, W.C.

Births.

Cameron-Young.—On May 14th, at Brightwell, Woodbridge Road, Ipswich, the wife of A. Cameron-Young, M.R.C.S., of a daughter.

Dwyer.—On May 14th, at 69 Middleton Road, Banbury, the wife of Hubert de Burgho Dwyer, M.R.C.S., L.R.C.P. Lond., of a son.

Hichens.—On May 14th, at Northampton, the wife of Peverell S. Hichens, M.D., M.R.C.P., of a daughter.

Spurrier.—On May 17th, at Pinehurst, Maidenhead, the wife of H. Spurrier, M.B., B.C. (nee Mary Cato), of a son.

Yin.—On May 12th, at Lydia, Leonie Hill, Singapore, the wife of Dr. S. C. Yin, M.B., M.R.C.S., L.R.C.P. (nee Bowyer), of a son. (By cable.)

Marriages.

Clatworthy—Gooding.—On May 15th, at St. Margaret's, Lee, John Hunter Clatworthy, M.D. Lond., of 145 Denmark Hill, London, younger son of Augustus R. Clatworthy, of Beccles, to Ethel Maud, younger daughter of Ralph Gooding, M.D., D.L., J.P., of 13 Church Terrace, Blackheath.

Huey—Jardine.—On May 15th, at Hampstead, Dr. J. Mackay Huey, 75, Holland Park Avenue, Kensington, late Med. Off. in Charge Staff and Dept., Castle, Cape Town, to Ethel Halliday, seventh daughter of the late Wm. Jardine, of Cape Town.

Longhurst—Jarratt.—On May 15th, at St. Peter's Eaton Square, Bell Wilmott Longhurst, Surgeon-Major R.A.M.C., eldest son of Sir Bell Longhurst, of The Woodlands, Barnes Common, and 28 Old Burlington Street, London, to Eleanor (Nellie), youngest daughter of the late William Otley Jarratt, Esq., of Hilderthorpe Lodge, East Yorks.

Deaths.

Legge.—On May 12th, at 45 Friar Gate, Derby, William Legge, M.R.C.S., J.P., aged 75.

Owen.—On May 18th, of post-influenzal disease of the heart, Annie Laura, wife of Edmund Owen, F.R.C.S., of 64, Great Cumberland Place, London, aged 45 years.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXIV. WEDNESDAY, MAY 29, 1907. No. 22

NOTES AND COMMENTS.

Telephones and Infection.

THE French Government have drawn a good deal of attention to the telephone as a possible source of infection by ordering all public telephones to be disinfected. This command followed a complaint made by a gentleman that he had contracted "skin trouble" from using the public instruments; but as we are not informed what the skin trouble was, nor what evidence connected it with the telephone, one cannot attach great importance to the mere assertion. Still a good journalistic sensation is being made of the fact, and the Post-Office and National Telephone Company in this country are being called upon to act in the matter. While, of course, it is eminently desirable that ordinary cleanliness should be maintained at all public call offices and in all instruments, the risks to users must be infinitely small, or a great deal of complaint would have been heard ere this. It is easily possible that one might contract scabies from the handle of an ear-piece of a telephone, but then one might contract it equally easily from any railway door handle or omnibus rail, and the people who would be likely to infect a telephone would be far less numerous than those who use ordinary public vehicles. The mouth-piece of the telephone, too, does not come in contact with the mouth, and though there may be an infinitesimal danger from the inhalation of dried secretions, it is a far smaller one than is incurred in a hundred other ways in pursuing the day's avocations. The telephone authorities should certainly see that their instruments are frequently washed and polished, and indeed since some representations were made to them by Dr. Collingridge, we believe they do so, but there is nothing in the conditions of the telephone service to make the skin creep.

Ambulance Accident.

THERE is a spice of irony in the unfortunate accident which happened at Hampstead Heath on Whit Monday, when the horses drawing a St. John's Ambulance Brigade waggon bolted into a crowd and injured eleven persons in various degrees, one child, alas! fatally. That the Brigade's emissaries should have been the cause of this series of mishaps when they went out to succour the injured is one of those sarcasms of nature which seem particularly undeserved. The voluntary organisation of persons into Samaritan corps to supply the place that State organisations should take redounds highly to their credit, and we are sure that no one will have anything but sympathy with them in this terrible contretemps. It might, however, be advisable to secure a more docile type of animal to draw the ambulances, as the conditions of such pleasure-resorts as Hampstead Heath on Bank Holiday are calculated to try the mettle of most horses pretty severely.

Raw Sausage for Delicate Children.

THE necessity for a little primary instruction for mothers in the feeding of their children was startlingly illustrated by a fact which came out in evidence at an inquest at Hackney last week. The subject of the inquiry was a three-year-old child who had always been delicate, and for whom the family doctor had advised a diet consisting principally of rice and milk. The child, however, seems to have had carnivorous instincts, and seeing her mother preparing some raw sausages, she clamoured to such purpose that the mother to satisfy her gave her half a one to eat. Asked by the Coroner whether she was in the habit of giving her children such delicacies, she replied that she did so when they cried, although she would not eat raw sausages herself. The jury returned a verdict of "Natural Death," but we cannot help thinking that the point in civilisation has been arrived at when it would be well to bring such actions as this of the mother under the head of culpable neglect. It is no compliment to the humanity of society that medical advice should be so glaringly neglected without some sort of penal consequence to the responsible person. The "Cry of the Children" is gaining much response just now; their cries for raw sausage might be included in the purview of the leaders of the movement.

Advantage of Co-operation.

ANOTHER example of what may be accomplished by the combined action of medical men was furnished at Banbury the other day. Dr. Innes Griffin, of that town, was called into consultation by the workhouse medical officer, Dr. Dwyer, to consult over the case of a pauper patient. The recognised fee in such cases was a guinea, but the guardians by way of economy, tendered only half that sum. A County Court action was brought by Dr. Griffin, who, however, found that he had no legal claim, and agreed to settle the matter out of court, as a guinea was tendered by defendants.

Subsequently a meeting of the profession was held, and a letter written to the Board of Guardians saying that as they had been informed that medical men had no legal claim against the guardians for consultations, they must decline to meet the workhouse medical officer till a satisfactory arrangement was arrived at. A discussion ensued at the Board meeting, and in the end a reply was sent to the profession that in future a guinea would be paid in all cases in which a consultation was invited. We cordially congratulate the profession of Banbury on the result of their action and in the method adopted. The bare-faced underpaying of medical services which public boards indulge in on one ground and another can only be stopped by the profession presenting a united and dignified front.

Doctor and Matron at Highfield Infirmary.

We have had reason several times to comment on the dangerous and pernicious doctrine held by some local authorities in the country as to the relative positions that should be occupied by the medical officer and the matron of a hospital or infirmary. The Workhouse Committee of the Liverpool Select Vestry is one of the said authorities whose action we have had to criticise on account of the unsatisfactory position which they accord to their medical officer at the Highfield Infirmary. We are very glad to see that the matter has not been allowed to drop, for in a re-organisation scheme which they have before them it is proposed that the chief executive officer of the infirmary shall be the medical officer, and that the matron shall be his subordinate. The point has not yet been definitely solved, but considering the evidence that one of the members has collected on the subject, and the prejudicial influence on the conduct and discipline of an institution which the placing of a matron in a position of authority superior to the medical officer always exercises, we fancy that there can be little doubt as to the final decision. Indeed, we are surprised at the Local Government Board sanctioning any other arrangement, because their views formed as the result of many years' experience are both strong and well known. The Highfield Infirmary, it is proposed, shall take the definite place of a hospital for sick paupers, instead of being as at present a kind of home, and such a change makes the change in constitutions we have indicated all the more imperative.

Protection of the Innocents.

If laws for the preservation of children were as many and as rigorously enforced as those for the preservation of game, a great national disgrace would soon be wiped off the slate, but in this country by ancient custom we have learned to value our pheasants more than the children of the nation. Some of the most pitiable of the cases helped by the Society for the Prevention of Cruelty to Children are the babies of young unmarried women, as these fall into the hands of unscrupulous persons; but in many instances information is received too late to save the innocent victims. There was a considerable diminution last year in the number of assaults and ill-treatment, but from carelessness and ignorance, overlying, burns, and so on, 1905 saw no fewer than 1,527 deaths. A memorial has been sent to the Prime Minister and the Home Secretary expressing a hope that facilities will be granted for the passing of the Prevention of Cruelty to Children Bill now before Parliament.

LEADING ARTICLE.

TRADES UNIONISM OR—AN ALTERNATIVE.

There are many manifestations of discontent abroad among the main body of the medical profession. Among the more significant of these is a growing tendency to protest against the payment of inadequate fees by public bodies. In several instances a strong stand has been successfully taken by local medical bodies against the under-payment of resident medical officers holding Poor-law appointments. Then there is the great question of the medical aid societies which seek to make a direct profit out of the services of their medical officers. The facts of the latter case have been so long before our readers that there is no need to do more than refer to them here. There is one point, however, in common, not only to both the foregoing matters but to others of the same kind, and to this point it is the present purpose to call attention. This special feature is the action of local professional bodies not only in issuing their protest against any particular contract of employment, but in warning medical men generally against applying for such posts. Indeed, a list of appointments vacant under such circumstances is now published week by week. The principle adopted in this instance is nothing more nor less than that of "picketing," which forms one of the most powerful weapons of trades unionism. It may be well, therefore, to remind ourselves that the weapon is used to maintain a recognised scale of wages at or about a level mutually agreed upon as a fair one by the parties to an employment contract. Should any dispute occur as to the fairness of the remuneration, then the trades unionist, failing other adjustments, ceases work. Should the vacant posts be sought by other men at a lower rate than that demanded by the strikers, then the latter are now legally entitled to warn the newcomers as to the terms of the dispute and bring reasonable persuasion upon them to stand aloof. Now, to all intents and purposes, *mutatis mutandis*, this is what medical men are now doing in various directions. They have adopted the principles, and, to some extent, the tactics of trades unionism. In so doing they have, in our opinion, done nothing derogatory to the traditions of the profession to which they belong. By a close and practical application of similar trades-unionism principles, the lawyers have attained a security of their professional interests that is simply phenomenal in its strength and comprehensiveness. For a layman to trespass on the province of a solicitor is to court speedy and condign punishment, whereas to act as an unqualified medical practitioner is in many instances to amass a large fortune at the cost of a deluded public and a wronged profession.

Under such circumstances, it is surely somewhat squeamish to raise the cry of trades unionism against men who are attempting the collective defence of their professional interests in a perfectly straightforward and honourable way. That accusation has been brought against the Wandsworth Branch of the British Medical Association because they have attempted to secure a just scale of fees from the local board of guardians. At a recent meeting of the last-mentioned body, the action of the local medical association formed the chief subject of discussion. The original dispute arose in consequence of a midwife having called in a medical practitioner to a difficult case and, the patient being totally unable to pay the doctor's fee (£2 2s.), application for it was made to the guardians. The gentleman called in was not, it appears, an officer of the guardians, who thought the fee rather high, and in consequence sent a communication to the local Association concerned asking if they were willing to accept a fee of 15s. for attendance in similar circumstances. In answer to this, the Medical Association asked the following fees: Visit (including any necessary prescription), day (7 a.m. to 7 p.m.), 3s. 6d.; night (7 p.m. to 7 a.m.), 7s. 6d.; attendance at cases of operative interference, £2; administration of anæsthetic, £1 1s. The *Tribune* in commenting upon this incident, says that it has created strong feeling on the part of some medical men in the district, who have condemned the tactics adopted by the Wandsworth branch of the British Medical Association as bringing the profession "to the level of a trade union." The sneer is characteristic of the attitude of a certain section of the medical profession who deal simply in destructive criticism with any proposal for collective defence. The cry of "trades unionism" has often been raised by such men, and has hitherto served its purpose. Now that the principles of that movement have been frankly adopted by so many medical bodies, the reproach implied by the application of that term is likely in the future to be considerably curtailed if not altogether abolished. Call the modern movement for collective defence and reform amongst medical men what we may, its advent should be hailed with acclamation by the members of a sorely-tried profession. In the meantime, local associations of medical men in various parts of the United Kingdom will do well to note the firm attitude taken by their Wandsworth brethren in the matter of Poor-law fees and emergency attendances under the Midwives' Act.

CURRENT TOPICS.

Law for Lawyers and Law for Medical Men.

IN our correspondence columns of the present issue appears a letter from Mr. Henry Sewill, pointing out the inequality of the law controlling qualified medical men as compared with that applied to solicitors. His letter is somewhat strongly worded, but not more so than is warranted by the facts of the case. The injury done to the public by the inditing of a business letter in legal form is infinitesimal. On the other hand the actual damage inflicted upon the health, the productive capacity, the happiness and, in some instances, the lives of His Majesty's lieges by a single specious quack advertisement may be incalculably great. Take the case of patent medicines claiming to cure chronic kidney disease, cancer and locomotor ataxy. None of these diseases are curable by any means known to scientific medicine, and any claim to effect a cure by any particular nostrum is necessarily based upon a falsehood and must therefore be fraudulent. Yet the law punishes vigorously and mercilessly the least infraction of a solicitor's province, while it permits the quack to go scot free on his evil career, in spite of the deadly havoc he is working on all hands. In this connection we include any person who advertises a drug or combination of drugs for the cure of specific maladies as an unqualified practitioner of medicine. Some day society will doubtless learn to appreciate at their proper value these will-o'-the-wisp remedies, and will exact from every man who professes to cure disease adequate proof of his special knowledge in the most difficult of all arts and sciences. Meanwhile, the most feasible way of informing the community as to the precise facts of quacks and quackery is by the agency of that truly British institution—a Royal Commission.

A Crimean Medical Hero.

ON the 12th of the present month the ranks of the few survivors of the immortal Charge of the Light Brigade were still further lessened by the death of Surgeon-Major Lancelot Armstrong. He belonged to the old 13th Light Dragoons, and as an army surgeon served throughout the Crimean war. He actually rode with the rest of his comrades when the order was given by Lord Cardigan to charge the Russian batteries. He stopped short of the guns to attend to the men of his regiment who were falling on all sides. In the face of a murderous fire Surgeon Armstrong did his duty to the wounded with a coolness and courage that should have gained for him the well merited distinction of the Victoria Cross. It seems unaccountable that such splendid heroism should have been overlooked in the distribution of honours, both at the time of the war and subsequently. Armstrong's name, however, is indelibly inscribed on the roll of medical men who have done their work nobly and well when called upon to do so in the service of the State.

Doctors' Mistakes.

WITH the issue of the annual report of the Metropolitan Asylums Board we are accustomed to see articles in various papers complaining of the high ratio of errors of diagnosis to the total admissions to the Board's infectious hospitals. The doctors who sign the notification certificates are supposed to be very stupid people not to be able to recognise scarlet fever, diphtheria, and typhoid fever when they are called in, and members of the Board themselves are often to blame for making censorious remarks on the subject. It is, however, one of the necessary conditions on which an isolation hospital works that it should receive cases, especially diphtheria cases, early, and if the medical men delay till all the symptoms of a disease are well established they will often be compelled to keep a patient at home for days or weeks. The returns this year show figures much the same as in other years, namely, a percentage rate of error for scarlet fever of 5.2, for diphtheria of 18.3, and enteric fever of 33.7 Medical men in practice know the enormous difficulties in diagnosing enteric fever in its early stages, and also the importance of removing a patient to hospital as early as possible, and they will not be disposed on the whole to think a ratio of a third particularly high, whatever laymen who glean their information after the event may believe. The necessity of early administration of antitoxin in diphtheria is shown by the figures which the Brook Hospital has kept from the beginning of the antitoxin period. These record that of 235 cases treated in the first day of disease, no cases died; of 1,441 on the second day, 4.3 per cent. died; of 1,600 on the third, 11.12 died; of 1,276 on the fourth, 17.2; and of 1,645 on the fifth day or after, 18.72 died. If these figures do not justify an error ratio of 18.3 in the diagnosis of diphtheria, it is difficult to say what would.

Red Cross Organisation.

THE unsatisfactory and disjointed condition of the voluntary societies formed to aid the sick and wounded in time of war has always been apparent in the past, but since 1905 the work of co-ordination and organisation has been going on so steadily that if a war were to break out it is probable that the charity of people at home would be administered in a more scientific way than ever before. The prime mover in this matter is the Queen, who has personally taken the question up, and after securing that there should be an amalgamation of all bodies into one society, and that that society should be the only channel between the public and the War Office, she has set to work to engage the support of the Lords Lieutenant and the leading people in every county. According to a speech made by Sir Frederick Treves at Lincoln at a meeting to inaugurate a branch of the society in that county, it appears that the Red Cross Society is about the only charitable body that does not require money, for the Committee have £172,000 invested, and the income produced thereby is ample for their wants in time of peace. But what is needed is to have a branch of the society in every place so that the money subscribed by people in time of war may be properly spent and applied to the best advantage. As examples of the waste of energy and philanthropy in the South African War, Sir Frederick instanced two experiences of his own, namely, that certain boxes sent out to him circulated round and round South Africa all the time he was there, and reached him only after his return to London, and again, that at Ladysmith, when the temperature was 103° and 105°, a large box of warm woollen mittens was sent him for the troops. But now that the society is really likely to be managed in a workmanlike way and the fullest play is to be allowed for local patriotism, it will be a great reproach to the practical genius of the race if the organisation is not well and truly laid in every corner of the land; all the more so as, at the Conference of the Red Cross Societies from all countries which is shortly to be held in London, we shall propably hear again the wonderful tale of how the Japanese made such Red Cross arrangements as succeeded in alleviating and succouring over a million patients during the war wth Russia.

Post-Graduated Work in Dublin.

IT is a matter for congratulation to all interested in the intellectual activity of the Dublin School of Medicine and the profession in Ireland to see the keen way in which facilities for post-graduate work have been made use of in the past few years. It is only three years since Trinity College led the way by organizing for the first time in Ireland a course of study for medical practitioners. The services of capable and inspiring teachers were secured, and the success attending their efforts has been shown by the increasing number of medical men who attend the successive courses. Last year, the Royal College of Surgeons arranged two courses of lectures and demonstrations, one in June and one in October. This year they have announced similar series, the material of nearly all the clinical hospitals being made available. The Catholic University School has followed suit; lectures will be given in Cecilia Street, and clinical teaching in the Mater Misericordiæ and St. Vincent's Hospitals. From Belfast also there comes news of the arrangement of a post-graduate course. The advantage to a busy practitioner of a few weeks at one of these centres of learning, seeing new methods, meeting old friends, and renewing old associations, is incalculable.

Sterilisation of Certain Degenerates.

THOSE having this subject at heart will be interested to learn that a Bill was introduced into the Legislature of the State of Indiana, read a first time on January 29th, 1907, and referred to the "Committee on State Medicine, Health, and Vital Statistics," and on February 6th, referred to the "Committee on Benevolent and Scientific Institutions;" passed by the Senate on February 27th, and finally approved by the Governor. The text of this Act is as follows:—"An Act entitled an Act to prevent procreation of confirmed criminals, idiots, imbeciles, and rapists, providing that superintendents and boards of managers of institutions where such persons are confined, shall have the authority and are empowered to appoint a committee of experts, consisting of two physicians to examine into the mental condition of such inmates.

Whereas, heredity plays an important part in the transmission of crime, idiocy, and imbecility. Therefore, be it enacted by the General Assembly of the State of Indiana, that on and after the passage of this Act, it shall be compulsory for each and every institution in the State, entrusted with the care of confirmed criminals, idiots, rapists, and imbeciles, to appoint upon its staff in addition to the regular institution physician, two skilled surgeons of recognised ability, whose duty it shall be, in conjunction with the chief physician of the institution, to examine the mental and physical condition of such inmates as are recommended by the institutional physician and Board of Managers. If, in the judgment of this committee of experts and the Board of Managers, procreation is inadvisable and there is no probability of improvement of the mental condition of the inmate, it shall be lawful for the surgeons to perform such operation for the prevention of procreation as shall be decided safest and most effective. But this operation shall not be performed except in cases that have been pronounced unimprovable. Provided, that in no case shall the consultation fee be more than three ($3.00) dollars to each expert, to be paid out of the funds appropriated for the maintenance of such institution.

Housemaid's Knee.

Of all the long list of trade maladies known to the public, there is probably no single one more popular than "housemaid's knee." The name goes straight to the very inwardness of the thing, and its mention flashes a vivid image upon the mind of the all-important man in the street. Instantly he pictures to himself a maid-of-all-work with a huge swelling in front of the knee as the result of washing many floors and front door steps. He knows the malady to be painful and crippling, but at the same time absolutely preventable. Give her a proper mat to kneel upon, and the hard-working maidservant will avoid what the doctors describe as "a painful inflammation of the bursa in front of the ligamentum patellæ." Curiously, the Departmental Committee of Inquiry into the question of compensation for industrial diseases has reported dead against housemaid's knee. Chimney sweeps may claim for cancer, stablemen for glanders, and many scores of other workers for various forms of damage arising out of their occupation. But the housemaid is left out in the cold, the chief reason being that the "knee" is avoidable "by the simple method of kneeling on a proper mat." Suppose the employer does not provide that mat and housemaid's knee ensues, why should not the employer be held responsible? If such a liability were enforced, it is clear that all decent householders would escape, inasmuch as they would be careful to provide kneeling mats for their servants' use. It is to be presumed that the Departmental Committee do not suggest that housemaids should, if necessary, buy their own mats. This decision runs counter to the humane tenor of the extension of employer's liability to domestic servants.

PERSONAL.

We have reason to believe that the health of Princess Victoria is causing her parents much anxiety. Now that the Princess has returned to this country a consultation will be held by several medical men of high standing.

Sir Thomas Naghten FitzGerald, C.B., of Victoria, who has lived in Australia for nearly half a century, is returning to his colonial home at Melbourne this week by the *Orontes*, accompanied by his daughter, Miss Kathleen FitzGerald.

Dr. Bertram Abrahams occupied the chair at the dinner of the Society of professional men, known as the Maccabeans, on May 22nd.

Professor G. H. F. Nuttall delivered yesterday the first of two lectures at the Royal Institution on "Malaria, Sleeping Sickness, Tick Fever and Allied Diseases."

At the Stepney Coroner's Court, on May 22nd, the late deputy coroner, Dr. King Houchin, was the recipient of a handsome testimonial, which had been subscribed for by the medical men in the East End of London, as a recognition of the manner he had carried out his duties for thirteen years.

The Postmaster-General has appointed Dr. W. B. Crawford Treasure Post Office Medical Officer for the western division, and Dr. W. J. D. Morris, for the eastern division, of Cardiff.

Dr. William MacLeod, M.B., Ch.B., has been appointed medical officer for Strath.

Dr. A. T. Stanton, demonstrator at the London School of Tropical Medicine, has been appointed second assistant at the Kuala Lumpur Laboratory, in the Straits Settlements.

Dr. St. George Gray, medical officer of Sierra Leone, has been transferred to Southern Nigeria as senior medical officer. Prior to proceeding to West Africa, Dr. Gray served in the West Indies for eleven years.

Dr. R. H. Kennan, medical officer of the Gold Coast Colony, has been promoted senior medical officer of Sierra Leone in place of Dr. T. Hood, who has been transferred.

Dr. E. Ryan, of Crumlin, was last week presented with an address and a purse of gold by the colliers of the neighbourhood. It bore the following inscription:—"Presented to Dr. E. Ryan, L.R.C.S.E., L.R.C.P.E., Crumlin, by the Llanhilleth Colliery workmen and others of Crumlin and District."

Dr. Donald MacAlister opened the session of the General Medical Council yesterday, at 2 p.m.

Professor Nuttall delivered his inaugural professional lecture at Cambridge on May 22nd, in the Armstrong Theatre.

Sir John Batty Tuke has been unanimously re-elected representative of the Royal College of Physicians of Edinburgh on the General Medical Council for the next five years.

At the memorial service on Saturday last for the late Sir Joseph Fayrer, physician to the King, His Majesty was represented by Sir Arthur Ellis, and among those present were Lord Strathcona, Sir Frederick Treves, Sir R. Douglas Powell.

Dr. J. Coote Hibbert, assistant medical officer of health for Newcastle, has just been appointed medical officer of health for Warrington.

A CLINICAL LECTURE

ON

THE TREATMENT OF PNEUMONIA. (a.)

By Sir JAMES BARR, M.D., LL.D., F.R.C.P., F.R.S.E.,

Senior Physician, Liverpool Royal Infirmary; Chairman of the Medical Faculty of Liverpool University; President of the Lancashire and Cheshire Branch, British Medical Association.

PART II.—(*Conclusion.*)

SLEEP.

It is most important that the patient should have a fair amount of sleep from the very commencement; there is nothing lessens the patient's chance of recovery so much as the exhaustion of the nervous system from want of sleep. There is no objection to opium in the early stage, and two or three 10-grain doses of Dovers' powder during the night often answer admirably. In alcoholic subjects a combination of opium and antimony answers well. Professor Waymouth Reid and Professor Macdonald have shown that morphine lessens the nerve impulse travelling along the phrenic nerve; when, therefore, the lung is engorged and the right side of the heart handicapped, I would avoid all preparations of opium, or only use morphine in combination with hyoscine and atropine, or strychnine. If sleep has been obtained in the early stages it is not difficult to induce it in the later. Sleep is absolutely necessary for the patient, and the sooner it is procured the better. A quiet restful sleep tends to lower the temperature, and on the other hand a high temperature is very inimical to sleep. The delirium of a low muttering character which frequently accompanies this disease is usually controlled by free ventilation, and the reduction of the patient's temperature, which is best effected by large ice-bags to the abdomen. Pneumonia complicated with delirium tremens is a very fatal malady. It is often difficult to draw a distinction between the delirium of pneumonia and alcoholic delirium complicating pneumonia; and acute or late delirium, by which appellation the complication is known nowadays, is more euphonious to the public ear than delirium tremens. These cases are marked by active, often violent delirium, delusions of sight and hearing, great tremor, irritability of the nervous system, and the knee jerks are generally absent. In such cases it is essential to keep the nervous system quiet and obtain sleep, but this is often a most difficult problem to solve, especially when the delirium tremens arises late in the pneumonic attack. There must be no mechanical restraint or any struggling with the patient, as thus fatal syncope is readily induced. I have often seen these patients become quiet when they were allowed to stand or walk about in a well-ventilated room. Under these circumstances the fall in the blood pressure and the lessened blood supply to the brain has a calming effect. When the patient has been induced to go back to bed, if it be in the early stage of the disease, and the pulse full and bounding, or small and firm he should have repeated doses of antimony and opium. If in a later stage with the pulse small, short and feeble, and with the lungs engorged and skin very moist, a hypodermic injection of hyoscine, morphine, and atropine answers better. A few whiffs of chloroform or the A.C.E. mixture often gives the sedative an opportunity of acting. To these patients I frequently allow two pints of beer or stout in the twenty-four hours as a sedative. It is not wise to entirely cut off alcohol from a patient bordering on delirium tremens. Under no other circumstances do I prescribe alcohol in pneumonia. Alcohol does not increase the power of the cardiac muscle, but merely lessens the peripheral resistance by producing vaso-motor paresis, an effect which cannot often be required, as the systemic blood pressure is usually too low without any assistance from alcohol. It also increases the diastolic tension within the ventricles and leads to cardiac dilatation. Alcohol dries the tongue, increases the delirium, and makes the sleep more perturbed. The good effects of abstention are well seen in those cases who have been overdosed when you abruptly cut off all alcohol. The delirium, restlessness, and parched mouth are replaced by quiet sleep and moist tongue. During the convalescence the patient may, if thought necessary, revert to his accustomed use of alcohol, but in great moderation.

DRUGS.

If the illness began with nausea or vomiting, it is well to wash out the stomach with a few tumblerfuls of hot water to which an equal number of teaspoonfuls of mustard have been added. The bowels should be cleared with a brisk calomel purge. In sthenic cases antimony is useful, and if there be much restlessness or delirium antimony and opium is a good combination. In no case should an acid mixture be given at the commencement. Quinine as an antipyretic agent has been very much over-rated, but in hectic temperatures due to mixed infection it is a valuable agent in large doses, and during convalescence it is a good tonic in small doses. If the pulse tension be very low, the expectoration liquid and profuse or prune juice in character, a mixture of chloride of calcium and perchloride of iron is suitable. The more scanty and sticky the expectoration at the outset the better the outlook, hence you should never give agents in the early stages to increase or loosen the expectoration. The phlegm comes from the spreading area, and not from the consolidated lung, hence I prefer the lime salts to increase the coagulability of the secretion and limit the spread of the mischief. In pneumonia in a case of bronchitic asthma with marked emphysema and abundant muco-purulent expectoration, I have had good results from a mixture of chloride of calcium and tincture of iodine. If there be a tendency to cardiac failure the best remedies are strychnine, caffeine, and digitalis. The latter drug has been vaunted as a specific in pneumonia, but I have never found it such, and

---

(a) Delivered at the Liverpool Royal Infirmary, May 7, 1907.

very rarely prescribe it during the acute stage of the disease. An antidote for the pneumotoxin would be much more valuable than any of the antiseptics, but unfortunately we do not possess such. In cases of mixed infection with streptococci I have found anti-streptococcal serum valuable. If there be any danger of collapse with profuse perspiration atropine should be injected. If there be any tendency to the formation of cardiac thrombi remedies which keep the blood liquid should be freely administered, such as a mixture of equal parts of liquor ammonii fort. and spiritus chloroformi, 5 to 10 minims every half hour or hour; also decalcifying agents such as citric acid, citrates of sodium and ammonium, lemon squash, &c.

The views which I have propounded regarding drug treatment in pneumonia do not command universal acceptance, and I have recently taken part in a controversy on the subject in the *British Medical Journal*. Dr. William Ewart in an interesting article on the "Principles of Treatment of Pneumonia," (*a*) holds that you should endeavour to keep the secretion in the air cells and bronchi as liquid as possible, so as to avoid as far as possible consolidation of the lung. In opposition to this view I hold that, *cæteris paribus*, in the acute stage of pneumonia, the more scanty and more sticky the expectoration, the more viscous the blood; the more lime salts and leucocytes it contains, the more favourable the prognosis; on the other hand, the more fluid and hæmorrhagic the expectoration, the more liquid the blood; the less the lime salts and leucocytes, the worse the prognosis. Acting on these views I have long ceased to prescribe carbonate of ammonia and other expectorants during the acute stage of the disease. Those cases of creeping and influenzal pneumonias where there is no proper consolidation are most fatal. The cardiac thrombosis is more frequently a sequel than a cause of cardiac failure; occurs chiefly in the right auricle and ventricle; is due to cardiac weakness, blood-stagnation, leucocytic destruction, and fibrin ferment, rather than to any great excess of lime salts. When the febrile process is over it is then well to use some agent to lessen the viscosity of the blood and liquefy the effusion in the alveoli. You all know how much importance I attach to the calcium salts in this disease, and for many years I have had to be content with clinical evidence as to the indications for their use, and the amount in the blood by the state of the expectoration and the coagulability of the blood, but now Dr. Blair Bell has provided us with an excellent and accurate method for determining the quantitative amount in the blood. So far as our observations have gone with this correct method it has supported my previous practice.

Similar views have been ably expressed by Dr. Auld (*b*) "that the pneumonic consolidation is Nature's method of localising the morbid process, and of curing the disease . . . Moreover, in cases of pneumococcus infection showing little or no tendency to pulmonary hepatisation—when the pneumococci run riot in the organism, so to speak, —the result is always grave, and indeed generally fatal." Dr. Auld writes me that "the results of his experiments on animals corresponded to those observed on man. It was only in those cases where a culture of moderate virulence was employed that hepatisation of lung was obtained in animals —a very virulent culture failed to give hepatisation, thus showing that when the organism of pneumonia freely enters the circulating blood, it prevents the pulmonary coagulation, whereas when it is capable of being localised coagulation follows. These injections were also made into the pleural cavities with the same results. The time element was also considered, as when the animal was killed after a moderately virulent culture hepatisation was observed to have begun, but after a very virulent culture this feature was absent, being replaced by a sanguineous serum." I consider these experiments of Dr. Auld of extreme value.

If the lung pass into the stage of grey hepatisation, with purulent infiltration and profuse expectoration, there is no remedy like terebene or some of the turpentine series. I have also found it invaluable in cases of abscess and gangrene of the lung and in bronchiectasis. During convalescence tonics are required.

The teeth, tongue, mouth, and even the nose should be kept clean with some antiseptic throughout the illness. The importance of keeping the mouth clean as a preventive measure is well exemplified in the so-called ether pneumonias which are due to the aspiration into the trachea and bronchi of foul secretions from the mouth. Before the administration of an anæsthetic the mouth should be well cleaned with some strong antiseptic. Pure brandy or whisky answers very well, but this mouth-wash should not be swallowed. An excellent mouth wash can be made with formalin, glycerine of carbolic acid, and eau de Cologne.

Pneumonia is a self-limited disease, and as a rule if we can only keep our patients alive for seven or eight days they get well. We must therefore inquire what are the causes of death in pneumonia in order to obviate them. It is well to see the danger signals ahead and try and steer the patient clear of them. We will now consider the class of patients who die from this disease.

There is a very heavy mortality during the first five years of life, and more especially during the first year. No doubt the vast majority of the cases included in the Registrar-General's returns are cases of broncho-pneumonia or capillary bronchitis, but yet after the second year true croupous pneumonia is not at all uncommon. The case mortality is variously stated from 30 to 50 per cent., and I have a shrewd opinion that the bronchitis kettle is to a considerable extent responsible for this excessive mortality. But independently of treatment, many of these little patients, after a long struggle, gradually succumb from failure of the right side of the heart. Why should this be? Their young hearts are healthy, and particularly sensitive, so that they will not stop on a slight provocation. In health the respiration affords great assistance to the right side of the heart in carrying on the circulation, but in diseases affecting the respiratory pump this assistance is diminished or cut off. If you observe a young child suffering from laryngeal diphtheria you will see that the resilient chest walls cannot expand against the atmospheric pressure; the diaphragm is pulled down, but the lower part of the sternum and the costal cartilages are pushed in so that the heart gets comparatively little assistance from the respiratory pump.

(See my paper on "The Effects of Respiration

(*a*) *Lancet*, Vol. I., p. 138, 1905.
(*b*) *Lancet*, Vol. I., p. 254, 1905.

on the Circulation," *British Medical Journal*, April 20, 1907.)

In capillary bronchitis and pneumonia where there is little variation in the dimensions of the lungs between expiration and inspiration, the same conditions apply though to a less extent.

The situation of the heart when the soft cartilages are easily pushed in by the atmospheric pressure prevents the blood vascular cavity from obtaining much relief. Moreover the stomach and bowels are frequently so much distended with gas, owing to too much food of an improper quality, that the diaphragm has got very little play, and thus the respiratory pump is still further thrown out of action. However, there is one point in favour of these young children, and even of those of less tender years suffering from pneumonia: their inspirations may appear short, shallow, and catchy, but there is frequently a considerable pause between the end of inspiration and the commencement of expiration which enormously assists the pulmonic circulation.

In children after the age of five years with strong chest walls, and in young adults, the surplus vital capacity, even when a whole lung is involved, is usually sufficient to tide the heart over its difficulties until resolution takes place. In women—and especially in pregnant women—the vital capacity is less and the mortality is greater than in men. With advancing years and rigid chest walls there is a gradual failure in the respiratory pump, and a corresponding increase in the mortality. However, there is a great difference in individuals, and some spare men keep a good pump even up to old age. In very old people, as was pointed out by Sir William Gull, pneumonia is frequently a mode of dying, and they die as comfortably from it as from any other disease.

The big, plethoric, pot-bellied man succumbs rapidly to an attack of pneumonia. How is this? Such men are not particularly prone to the disease; the pneumococcus has no special predilection for fat; the disease is not more intense than in lean persons, except that the non-conducting layer of fat is apt to maintain a higher internal temperature. The typical John Bull is never ready for a fight of any kind, and although, as Lord Rosebery says, the Englishman generally tumbles on his feet, in this process of tumbling an enormous number go under the sod. These fat, flabby men cannot bear to be hit either under or over the belt, as their wind is easily knocked out, and a moderate attack of pneumonia throws the respiratory pump out of gear. The best treatment for these individuals is prophylactic; you should start months or years beforehand to reduce their corporations, and strengthen their fat, flabby right hearts.

There is another condition where the individual has got a fatty degenerated right ventricle, but a good respiratory pump. I have known many such cases going about their ordinary business for years with an extremely irregular pulse and a barely appreciable first sound over the right ventricle. Of course such patients are apt to succumb to any acute illness, but it is marvellous how their good respiration carries them safely even through a mild attack of pneumonia.

Patients suffering from emphysema are not good subjects for an attack of pneumonia, but the right side of the heart is usually hypertrophied, and does not stand in much need of respiratory assistance, so if there be no accompanying bronchitis, it may suffice for pneumonia of one lobe.

In diabetes there is frequently much emaciation of the chest muscles, a feeble respiratory pump, and a weak heart, conditions which favour a fatal determination.

In advanced kidney disease there is uræmic poisoning, a tendency to pulmonary œdema, indicative of right cardiac failure. Both acute and chronic alcoholism lead to cardiac asthenia, and the frequently associated abdominal distension interferes with the respiratory pump, so such cases are very liable to rapidly succumb from cardiac failure, accompanied by a large *ante-mortem* clot in the right side of the heart. The case is quite different with the gouty individual, his heart is usually hypertrophied and healthy, and if there be no kidney mischief he stands an attack of pneumonia well

There are certain cases which seem to fall victims to the intensity of the poison, but the vast majority of the deaths are due to cardiac failure arising from want of proper care and assistance owing to a defective respiratory pump. Mere carbonic acid poisoning is scarcely ever a cause. In bad cases of emphysema with bronchitis the patient is often livid for weeks, but so long as the right heart does not fail there is no danger from the mere lividity. It is true that in carbonic acid poisoning there is a general rise of arterial pressure and secondary overloading of the right side of the heart, but in pneumonia this sequence is prevented by the vaso-motor paresis. The overloading of the right side which takes place is due to failure of the heart and of the respiratory pump. At the very commencement of an acute pneumonia, with a severe stabbing pain in the side, the patient's face is often extremely purple and congested. This is not due to any obstruction in the lungs, as is shown by the large, full, bounding, relatively high tension pulse, but arises from the fact that the patient cannot use his respiratory pump owing to the sharp pleuritic pain. These are the cases where the removal of 10 to 20 ounces of blood from the arm affords immediate relief, but *Cui bono*? A good dose of opium or opium and antimony has a similar salutary effect by relieving the pleuritic pain and enabling the patient to put his pump in action.

PREVENTION OF CARDIAC FAILURE.

Cardiac failure is the proximate cause of all cases of somatic death; anyhow we would scarcely say the patient was dead until the heart ceased to beat. What are the causes of cardiac failure in pneumonia? A certain number of hearts have such degenerative vessels and muscle walls that they fail under the slightest stress, or cease to beat under any marked inhibition. We are never likely to be able to prevent such deaths unless by prophylactic measures. The large majority of hearts, however, make a desperate struggle for continued existence; the failure takes place from (*a*) granular degeneration of the muscular fibre induced by continued high temperature and toxæmia; (*b*) low arterial pressure which prevents proper nutrition of the heart, and produces a syncopal condition, the interference with the proper action of the respiratory pump from any cause leads to overloading and ultimate failure of the right side of the heart. Our indications for treatment, therefore, are (*a*) to lower the temperature and control the inflammatory process at the earliest possible period before great stagnation of the blood and extensive hepatization have taken place, and thus preserve as far as possible the integrity of the respiratory apparatus; (*b*) to maintain the systemic blood pressure; and (*c*) to keep the respiratory pump in action by lessening the frequency and increasing the depth of the respirations.

The diet should be extremely light and consist chiefly of milk; about two pints of milk, two or three pints of barley water, or whey, or plain water and about six ounces of syrup of glucose make an excellent diet in the acute stage. One of the greatest difficulties in private practice is to control the diet; the public have been educated in the belief that great quantities of nourishment and stimulants are necessary, and consequently you frequently find the abdomen enormously distended with flatus which prevents free play of the diaphragm.

In conclusion I wish to strongly impress on you that pneumonia should always be looked upon as a serious disease. I know of nothing more terrible than to see the breadwinner of a large family cut off in a few days by this dire malady, so every medical man in dealing with this affection should feel the responsibility of a human life in his hands. Unfortunately some men never see a danger signal until the patient is dying, and then they get thoroughly alarmed when it is too late to avert the catastrophe. Early recognition and prompt treatment would save many a valuable life.

NOTE.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by Arthur E. Giles, M.D., B.Sc. Lond., F.R.C.S., Surgeon to the Chelsea Hospital for Women; Gynæcologist to the Prince of Wales' Hospital, Tottenham. Subject: "The Developments and Dangers of Extra-Uterine Pregnancy," with illustrations.*

ORIGINAL PAPERS.

THE TREATMENT OF ALBUMINURIA AND ECLAMPSIA OF PREGNANCY. (*a*)

By ED. OCTAVIUS CROFT, M.D.,
President of the North of England Obstetrical and Gynæcological Society.

THE author, after reviewing the various methods of treatment which had been carried out from time to time, said he considered that we had not yet the materials at hand for a scientific basis of classification of the causes and indications for treatment. Further advances, he thought, must be made by the pathologist and obstetrician in conjunction. Our present position as regards treatment is somewhat more advanced than twenty years ago, in that we pay more attention to the presence of an unknown toxæmic condition which we attempt to deal with directly. He ventured to hope that ultimately the medical treatment of the disease will improve in efficiency to the extent of largely diminishing the necessity for active obstetric interference in most cases, and mere palliative treatment of the convulsions when such supervene. In speaking of pregnancy associated with pre-existing nephritis, he urged that the pregnancy should not be interrupted, until very thorough general treatment had been adopted, as many cases improved rapidly and completed the pregnancy without serious trouble. Cases of chronic Bright's disease with pregnancy were quoted, in whom treatment was not attempted, and who developed serious eclamptic attacks.

In considering *Albuminuria of pregnancy apart from eclampsia*, he urged the importance of complete recumbency, warmth, milk diet, and eliminative measures. The pregnancy need not be interrupted until indications were present that the disease was not under control. Spontaneous abortion from death of the fœtus often rendered operative interference unnecessary. In the event of the necessity arising, then Dr. Croft advocated the gentlest method. Rapid dilatation and evacuation under deep anæsthesia (especially ether) he thought was bad practice.

The treatment of the pre-eclamptic state required more vigorous attention to elimination, and rectal and gastric lavage, followed by saline injections, and hot packs, were useful. Pilocarpine might also have its use in this stage, but it was dangerous during the eclamptic attack. Diaphoresis was more safely produced by the hot pack. The recognition of the pre-eclamptic stage gave us warning and time to adopt energetic measures. There is now no doubt that the pregnancy should be terminated by rupture of the membranes. In the absence of convulsions time may be given for dilatation to occur. Accelerative measures may be employed if necessary.

The author discussed the *Treatment of the eclamptic attack*, and the various methods directed towards (1) the elimination of the poison; (2) controlling the actual convulsions; (3) the obstetric procedures for emptying the uterus. He asked for opinions on venesection, followed by saline infusion, intravenous or subcutaneous. He approved of these, as well as purgation by saline rectal injections and subsequent lavage. He had not found thyroid effectual, but more evidence was required in this respect. For pyrexia, he preferred the application of cold to antipyretic drugs. He instanced two cases where the temperature rose to 107° in a few hours. The operation of renal decortication required further evidence to justify its employment.

He thought the control of the convulsions by chloroform as a routine practice required reconsideration. He did not agree with its prolonged administration. The indications for morphia also should be clearly defined. It undoubtedly in many cases controlled the convulsions, but he doubted whether it should be given when coma is well marked.

Regarding obstetric measures, he did not favour accouchement forcé, nor was Cæsarian section in his opinion ever necessary. Rupture of the membranes, dilatation of the cervix, preferably with the fingers if the dilatation did not occur naturally, and accelerative measures, forceps rather than version, was good practice.

He did not advocate mechanical dilators on the Bossi principle. He thought they were clumsy and dangerous substitutes for the trained and sensitive fingers of the obstetrician. Dr. Croft illustrated his remarks by notes of a series of cases.

(*a*) Abstract of paper read before the North of England Obstetrical and Gynæcological Society, May 10th, 1907.

ON THE EXAMINATION OF THE URETHRA AND BLADDER BY THE ELECTRIC LIGHT. (a)

By ANDREW FULLERTON, M.D., F.R.C.S.,
Hon. Assistant-Surgeon to the Royal Victoria Hospital and to the Belfast Hospital for Sick Children.

PART I.

THE urethroscope consists essentially of a metal tube with a pilot to facilitate its introduction. The light from a small electric lamp is reflected by a mirror on to the surface to be examined. By means of a small glass door, armed with a bayonet catch attached to the tube end of the instrument, the latter can be rendered air-tight and the urethra can be distended beyond the end of the tube by a bellows such as is used for administering chloroform by means of Junker's apparatus. This bellows is attached to a lateral tube placed on the distal side of the glass window. By unlatching and turning this back, applications can be made to or operations performed on any portion of the urethra. Two varieties of instruments have been used in these observations, the aero-urethroscope of Hurry Fenwick, and a modification of the same by Wyndham Powell. The latter instrument is provided with a condensing lens placed between the electric lamp and the mirror, and gives a much greater illumination than is possible with the former. The older instruments were devoid of the inflating mechanism, but distension of the urethra gives such an immensely superior view that most surgeons prefer this important modification. Several sizes of specula are necessary. For the examination of the urethra in front of the membranous portion, tubes about 4½ inches long are used. A shorter speculum, suitable for the first few inches of the urethra (about 2½ inches long) is very convenient for operative work in this region. For the urethra behind the compressor muscle a longer tube is necessary, and for this purpose Mr. Fenwick's instrument, curved somewhat like a large and short catheter, is used. This has a fenestra just proximal to the bend, which allows the verumontanum and neighbouring portion of the posterior urethra to be seen. This prostatoscope, as it is called, is more easily introduced than a long straight tube. The greater the calibre of the speculum, the better, of course, is the view obtained. If the meatus externus is very small, it can be enlarged in a downward direction by a tenotomy knife, after thoroughly cocainising the part. This causes very little discomfort to the patient. The same procedure may be adopted prior to using the cystoscope, if necessary. I would remind you that the urethral canal is far from being uniform in calibre. On examination with the aero-urethroscope, a number of annular constrictions can be clearly seen. These may readily be mistaken for commencing strictures instead of the normal condition. The electric current for the small lamps may be supplied by a battery, and the form I have used with much satisfaction is a lithanode accumulator with six cells, four of which are sufficient for ordinary purposes. A rheostat is necessary to regulate the strength of the current. The lamps for the urethroscope take a current of about 8 volts, while a current of about 7 volts is usually sufficient for those of the cystoscope. If the current from the main is used a resistance box or a transformer is required to reduce the current to the necessary strength. For myself, I prefer the lithanode battery, which works well if charged regularly about once a month. It is portable, simple, and convenient, and has not once failed me. To examine the anterior urethra, a speculum of suitable size, armed with its pilot, is selected and lubricated with sterilised vaseline, oil, or a preparation of glycerine, water and gum tragacanth. It is carefully passed down to the membranous urethra, and the pilot withdrawn.

The light-carrying portion of the instrument is now attached to the speculum, and the orifice of the membranous urethra can be seen, after mopping out excess of fluid, as a small depression with folds radiating from it. Under ordinary circumstances air will not easily pass beyond this point. If gonorrhœa has been present, however, air will often pass very readily, and, reaching the bladder, produce a characteristic sensation to the patient which causes him to start, more from surprise than pain. The bulbous urethra and occasionally the orifices of the ducts of Cowper's glands may be seen on withdrawing the instrument a little, and admitting a small quantity of air. The mucous membrane can be carefully inspected from behind forwards, and any abnormality noticed. The ducts of Littré's glands will be seen, especially along the roof towards the anterior half of the penile urethra. These are sometimes infected in gonorrhœa and discharge pus from their interior. This form of urethritis is very difficult to cure. Further forward you will observe a ring or fold of mucous membrane at the base of the glans, situated either in the roof or circularly. This is the valve of Guérin. In front of this and situated in the roof, about half an inch from the meatus, is the so-called lacuna magna, the duct of a gland similar to those seen further back. The portion of the urethra in the glans penis is somewhat dilated, and forms what is known as the fossa navicularis. This fossa can be easily inspected by placing the nose of the urethroscope, without a cannula, just over the meatus and distending gently with air. By this means I have recently seen two cases of stricture in the fossa navicularis preventing the introduction of the smallest catheter. Along the course of the urethra in cases of chronic gleet will frequently be found thick, vascular, inelastic areas, and more rarely granular patches, or papillomata. To deal with these they are first accurately located. The window is then unlatched, so as to allow of the passage of the appliances necessary for treatment. A few cases will better illustrate what I mean.

Case 68, a male, æt. 32, with a history of gonorrhœa ten years ago, suddenly began to bleed from the urethra, and to pass dark, porter-coloured urine. This continued for six days, when he was admitted to the Royal Victoria Hospital. On the night after his admission, he lost a large quantity of blood, and showed the constitutional symptoms of severe hæmorrhage. Next morning, after injecting adrenalin into his urethra, I passed the urethroscopic speculum and discovered several small papillomata, about 2½ inches from the external meatus. With a short speculum, and a curette such as is used by ophthalmic surgeons for cysts of the eyelids, I was able to nip the growths between the two instruments and so remove them. There was a large calibre stricture immediately behind the papillomata. The bleeding ceased immediately, and has not recurred. The blood had also passed back into the bladder, which was seen by the cystoscope to be healthy. Note that the colour of the urine was dark, and that it did not come from the kidney as dark blood is usually supposed to do.

Case 64 is a troublesome patient. He is æt. 26, and has suffered for many months from chronic gleet. With the urethroscope, Littré's glands are seen to discharge pus through their open and inflamed ducts. He is being treated as follows: Nitrate of silver is fused on the end of a fine wire and passed into the ducts. He improves slowly, but at the end of six months' treatment he is still a patient. He had also a posterior urethritis, which appears to be now quite well as the result of instillations of nitrate of silver directly to the part. The long prostatic tube is rather a dangerous instrument, as its fenestra tends to injure the verumontanum and the delicate mucous membrane of the prostatic urethra. The following cases illustrate its use:—

Case 73, a male, æt. 34, fell six months ago on a nail which penetrated his perineum for an inch or more. Three or four weeks later an abscess formed and burst. Shortly after this urine began to leak from the perineal wound during micturition, and has continued to do so every since. He passes curdy matter in his urine, and lately he has noticed swelling of his legs, and puffiness about his eyelids. For the latter condition he was admitted under the care of Dr. Calwell. On examination there was found a fistula in his perineum, just behind the scrotum. The prostatoscope showed pus welling up from the floor of the prostatic urethra through an opening there. The prostate *per rectum* could be felt hard and nodular on both sides. No tubercle bacilli have been discovered in his urine, though Dr. Houston found his opsonic index below normal (.6). The pus could be seen with the cystoscope to fall back into the bladder in flakes and to lie in a heap at the base. Dr. Houston suspected tuberculous bladder or kidneys, but before injecting tuberculin, asked me to catheterize the ureters. Clear urine, loaded with albumin and casts, was obtained from both sides, showing the case to be one of chronic Bright's disease, with the complication in the prostate above referred to. Injections were therefore not advised.

(a) Being a paper read before the Ulster Medical Society on February 28th, 1907.

Mr. Hurry Fenwick mentions some cases of chronic posterior urethritis aggravated by an enlarged verumontanum, which he removes in selected cases. I have, following his directions, in a very protracted and obstinate case, removed such an enlarged verumontanum, and examined sections of it microscopically. It resembles Mr. Fenwick's case figured in his book on "Obscure Diseases of the Urethra." The patient states that he is much improved since the operation. I need hardly say that cases in which this procedure is necessary are rare. It does not seem to interfere with the sexual apparatus.

I have seen one case of ulceration of the prostatic urethra due to tubercle extending from the epididymis of the right side.

Case 61, a male, æt. 22, began to have frequency of micturition five years ago. He has become progressively worse and has now to pass water almost every half-hour. He occasionally passes blood and slimy matter, and his prepuce is macerated from constant dribbling of urine. His prostatic urethra is raw and bleeding, rendering it difficult to see the surface except for a second or so. I can find no evidence of tubercle in the bladder itself. *Per rectum*, the prostate and right vesicula seminalis were felt nodular and thickened. As tuberculous ulceration of the urethra is exceedingly rare, I have thought it desirable to mention this case.

Having mentioned these few cases to illustrate the lines on which investigation may profitably be conducted with the urethroscope, I now pass on to the consideration of the main part of my subject, namely, the examination of the bladder and ureteric orifices with the cystoscope. The instrument consists essentially of a lamp placed in the beak of a tube shaped almost like a Coudé catheter, with a prism placed on the proximal side of the bend, and a telescope which transmits the image. The prism serves to reflect the rays of light from the object examined so that they pass through a system of lenses and are easily perceived by the observer's eye. The lamps which are now used are the so-called "cold lamps," invented by Löwenstein, of Berlin. They appear to be ensheathed in asbestos, and, if used with ordinary care, do not burn the mucous membrane of the bladder, as the older variety were very apt to do. The current is supplied by a battery or from the main, with the same precautions as is the case of the urethroscope. Before introducing the instrument it is necessary to render it as aseptic as possible. As boiling ruins the cystoscope, some other method must be adopted, and the following may be relied upon to accomplish the desired result. The instrument is placed beak down in liquefied carbolic acid contained in a narrow vessel which allows the fluid to reach almost, but not quite, to the ocular end. It is then immersed in methylated spirit, which removes the carbolic acid. Finally it is washed with boiled water and dried with sterilized wool or gauze. For lubricating, oily material must not be used, as that would tend to grease the prism and obscure the view. The lubricant must mix readily with water, so that it comes off easily when the bladder is reached. Glycerine is an unsatisfactory lubricant, and I have therefore substituted for it a mixture of glycerine, water and gum tragacanth the consistence being about that of treacle. A similar mixture, containing in addition oxycyanate of mercury and called Melzer's catheter purin, is used by Professor Casper, of Berlin. The parts should be rendered thoroughly clean before the cystoscope is passed to minimise the ever-present danger of microbic infection. Even with the precautions just described, I have several times seen rigors, happily evanescent, occur, especially if there has been any source of infection in the urethra or bladder. In cases of tubercle of the bladder the danger of setting up a fatal cystitis is not inconsiderable; and much manipulation or examination of these cases is unnecessary and harmful. In retention of urine in patients æt. over 50, and in carcinoma of the bladder, the risks of infection are so great that extra care, if that is possible, should be taken, if it is found necessary to use the cystoscope.

As to the use of a general anæsthetic, I am opposed to it, except in rare cases, for the following reasons: (1) The risks of the anæsthetic itself. (2) The subsequent discomfort and sickness which are frequent. (3) Under an anæsthetic the secretion from the kidneys is disturbed, and, if it is necessary to catheterize the ureters, the antecedent starvation alters the character and amount of the urine secreted. (4) Many patients will hesitate, especially in private practice, to submit to an examination under an anæsthetic, unless they are satisfied that the latter is absolutely necessary for manipulation, which I hold is not the case in the large majority of instances. (5) The pain inflicted upon the patient is, as a rule, insignificant. I have the testimony of a young medical man, whose ureters were catheterized, to prove that, beyond an unpleasant sensation in the urethra, no pain was experienced. In some difficult cases, and perhaps in young girls, it may be advisable, but is rarely absolutely necessary. Local anæsthesia is, however, very useful and desirable. For this purpose cocain may be applied to the meatus in both sexes, but I rarely inject cocain into the urethra. In the *British Medical Journal* of a few weeks ago, a case of death from this cause was reported, and I have seen in my own practice alarming symptoms follow its use for this purpose. Eudrenine, a mixture of eucaine and adrenalin, is much safer and is efficient. It is prepared by Parke, Davis, and Co., and put up in small sealed glass tubes. The preparation of the bladder is the next step in the examination. If the urine is clear, it forms an excellent medium in which to examine with the cystoscope. I have frequently catheterized the ureters in the patient's own urine, without washing out, thereby simplifying very considerably the operation. In most cases, however, it will be necessary to wash out, using for this purpose sterile water or boric lotion. If cystitis be present, or if pus or blood be present in any quantity, it will require much care and patience to render the bladder sufficiently clean to obtain a satisfactory view of its walls and the ureteral orifices. If there is much hæmorrhage from the urethra or bladder, I usually inject adrenalin and water and leave it in for about fifteen minutes. There may be some blanching, but definite information is often afforded, and the ureteric orifices can usually be seen. The proper quantity of fluid to be left in the bladder for cystoscopic purposes may be stated as from five to ten ounces. If more is introduced, the apex of the bladder will disappear from view, and the ureteral lips become thin and stretched; if less, the folds of the lax mucous membrane may obscure the openings of the ureters or other objects which it is desirable to see. I have, however, frequently had to be satisfied with a distension of from two to three ounces, and in one case I succeeded in passing a ureteral catheter in a female bladder which would hardly retain even three ounces. The position of the patient may be the recumbent, with a hard pillow under the pelvis, or the lithotomy. I have become accustomed to the former and therefore prefer it; but the latter is, perhaps, more convenient for the surgeon.

The instruments which have been used in these observations are those of Nitze, and they answer all practical purposes. I hope, however, in the near future, to make a trial of some of the newer makes, which have recently been placed on the market. In the meantime, I can recommend Nitze's instruments, which I have used now for several years. For catheterizing the ureters a modification of the ordinary cystoscope is used. A channel is attached to the instrument, so that a small catheter may run in it and project under the eye of the operator when the cystoscope is in the bladder. The angle at which the point of the catheter projects can be regulated by a screw at the ocular end, which raises or depresses a small metal lever at the distal end of the instrument. I have used Nitze's catheterizing cystoscope in forty-two cases during the last twelve months, and have to record only one failure. This was in Case 59, a male, æt. 55, whose bladder wall was becoming invaded in a late stage of cancer of the rectum. The point of the ureteral catheter would only just engage the openings of the ureters. By no manipulation could I get it to proceed further. In all the other cases the operation was satisfactorily accomplished usually in a few seconds.

(*To be concluded in our next issue.*)

THE TREATMENT OF GOUT BY THE INGESTION OF COMMON SALT-CONTAINING WATERS. (*a*)

By Leonard Williams, M.D., M.R.C.P.,
Physician to the French Hospital in London; Assistant Physician to the Metropolitan Hospital.

It would seem necessary to begin this paper by explaining what I mean by gout, and what I mean by common salt-containing waters. By gout I understand that disease of disordered metabolism whose clinical manifestations appear chiefly in the joints, the arteries and the kidneys. Beyond this it does not seem expedient to venture, though I must not be understood to suggest that the disease does not manifest itself in other organs or systems. I am quite aware that by adopting this attitude I am evading a difficult question, but as it is no part of my present purpose to attack that question, and as the majority of us agree as to what is meant by the term gout or goutiness, I am content to leave the matter thus. By common salt-containing waters I mean natural mineral waters which contain common salt to the extent of one per mille or upwards. Many of these waters are, I am aware, often classed under other designations, such, for example, as sulphur waters, but for my present purpose the fact that a water contains chloride of sodium to the amount indicated, suffices to bring it into my category, whether or not the therapeutic value of the water is usually attributed to the presence of some other ingredient.

Having thus cleared the ground of any misunderstandings which might arise from the title, I would like to premise what I have to say by reminding you how little we really know of the action of natural mineral waters. That they are active beyond anything which an analysis of their mineral constituents would lead one to expect, we all know. That they are active in directions which are often surprising, we also know. These activities and their nature still present attractive problems to those who are interested in this matter. Comparatively recently radio-activity has been added to the number of positive factors which may aid in the solution of the problems to which I refer. I say *one* of the factors advisedly, because it is quite evident that the comprehensive claims which have been put forward in favour of radio-activity in explanation of the efficacy of chemically indifferent waters will scarcely bear examination. For it is obvious that if this was the only weapon, or, indeed, the most potent weapon, employed in Nature's laboratory for endowing waters with therapeutic properties of obscure origin, then it would be quite easy for us to imitate Nature's methods by adding small quantities of salts of uranium to our laboratory preparations. We must admit then that in spite of radio-activity, the real nature of the subterranean processes are, so far as our present knowledge goes quite inexplicable. The matter, shortly put, seems still to stand thus: Judged by ordinary pharmacological standards, chemical salts which appear in natural mineral waters are endowed with a degree of therapeutic activity very much superior to that of the same salts as dispensed by the chemist. I do not think that there is any instance of the converse of this proposition being true. I do not think, for example, that there is any instance of a chemical salt which is known to be active when administered internally, losing or abating any portion of that activity by the fact of its presence in a natural mineral water. Instances of hyper-activity are familiar to all. The waters of La Bourboule, for instance, though they contain a very small quantity of arsenic (.028 per mille), have proved themselves beyond all doubt to be specially efficacious in conditions in which arsenic is indicated. Similar instances, drawn from sulphur waters, and more especially perhaps, from iron waters, would be easy to adduce. But perhaps the best examples, because they are most easily appreciated, are those afforded by the natural waters which contain purgative salts, such as Carlsbad, Marienbad, Chatel-Guyon and Brides-les-Bains. Of these, that which shows the greatest quantity of analysable purgative salts is Marienbad, which contains 350 grains, *i.e.*, considerably less than one ounce of sulphate of sodium per gallon, a quantity which is, of course, quite insufficient to account for its carthartic properties. It would be easy to multiply such instances of what, when regarded from the laboratory standpoint, must be called the hyper-activity of salts as found in natural mineral waters; and in the absence of any single instance of sub-activity, we are justified in assuming that a natural mineral water which contains a chemical salt is at least as active in respect of that salt as a solution of the same strength artificially prepared.

So much being granted, let us briefly consider the position which chloride of sodium occupies in the physiological processes. Inasmuch as it is a constant constituent of the tissues, common salt is obviously necessary to life. But it is so in a very much smaller degree than is usually supposed. The organism requires a certain quantity (estimated at 30 to 40 grains a day), but anything over and above this quantity is quickly excreted. The surplus, so far from being advantageous as many of us have been taught to believe, though it may act to some slight extent as a diuretic, is, in health, practically inert; while in certain cases it is very deleterious. The salt when present in normal quantities assists in the osmotic processes which are continually taking place, and it is believed to act, if not as an antiseptic, then certainly in diminishing the toxicity of certain poisons. In illustration of this antiseptic influence we are reminded that during acute illnesses all the chlorides are retained in the system, to be discharged *en masse* when convalescence sets in; and it is now believed that they act, as opsonins act, by rendering the infective agent better suited to the attentions of the phagocytes. If, therefore, the chlorides can ever be regarded as curative agents, their proper sphere would seem to be the acute specific diseases, in which, so far as I am aware, they are seldom or never employed. It was at one time believed that serious consequences were liable to follow if an individual or a community could not obtain free access to common salt. M. Widal, (*b*) whose work in connection with the chlorides has deservedly obtained from him an even wider reputation than his work in connection with the reaction of the blood in typhoid, has shown that this is the very reverse of the truth. Not only have there always been vigorous communities who never salted their foods, but experimental researches conducted on

---

(*a*) Paper read at a meeting of the British Balneological and Climatological Society.

(*b*) "La Cure de Déchloruration" (Baillière, Paris).

himself, his patients, and his friends, have conclusively proved that virtual deprivation of common salt may continue for some months and even years, without causing any difficulty whatever. Under these conditions the amount necessary for the proper performance of the physiological processes is retained by the tissues and the organism refuses to part with any, until more is supplied. Nature does not throw away her dirty water until she has clean.

The chlorides are normally excreted by the kidneys Where there is great intestinal activity some portion passes with the fæces, and, under the influence of sudorifics, the skin aids in their elimination. The part played by the two last-named emunctories is, however, accessory only, and it has been conclusively shown by Widal and others that a very slight degree of renal inadequacy will give rise to a retention of chlorides. Of all the urinary constituents the one which seems to find the greatest difficulty in passing the portal of the kidneys is the chloride constituent. We have already seen that in actute specific fevers the retention of the chlorides may be regarded as a defensive measure, deliberately adopted, but there can be no doubt that in other morbid states such retention is not only not helpful, but is, on the contrary, in the highest degree harmful. When from any cause a renal inadequacy is present, according to Widal (whose observations have been confirmed by a great many observers) what happens is this. The chlorides, unable to force the renal exit, are retained in the blood. It is impossible for this fluid to tolerate them in more than a certain proportion. The surplus is therefore passed into the tissues. Being deliquescent, the salts, as soon as they reach the tissues, attract water, and œdema becomes established. This œdema is at first slight, and is to be recognised clinically only by very careful comparison of the patient's weight. It is deep-seated, affecting by preference the solid organs, and among these organs the kidneys are the most likely to be involved. A kidney which is œdematous, even though it be so to a very slight extent, is obviously a very much less efficient excretory instrument than one which is intact. Thus, to the retention of chlorides, and directly consequent upon such retention, we have superadded the retention of other substances, many of which are grossly and notoriously toxic. If now, the ingestion of chlorides be continued in what may be called the ordinary quantities, it is evident that they must accumulate in the system, with the result that the œdema which at first was slight and difficult of recognition, soon becomes general and obstrusive. Widal has shown that in cases of œdema depending upon renal disease, it is quite possible to cause the disappearance of the fluid by the simple expedient of withholding common salt, and to cause its reappearance by reinstating chlorides in the dietary.

So much, then, for some of the possible consequences of taking common salt in any but the smallest quantities where there is any reason to believe that renal elimination is defective. The subject is large and very attractive, and I have been sorely tempted still further to dwell upon it. I must, however, refer the curious to Widal's book, and return to my thesis by enquiring what are the conditions in which renal inadequacy is most liable to show itself. A broad view of this question compels the answer that a large, a very large proportion of the morbid conditions in which we fear anything like a sustained dereliction of duty on the part of the kidneys, are those which are usually associated with the gouty diathesis. So much is this the case that chronic interstitial nephritis is often called "gouty" kidney, and we know that a truly chronic gouty manifestation, whether it be articular, vascular, cutaneous, or what not, will in many cases pass into a nephritis of the chronic interstitial variety before the curtain finally falls.

If the ingestion of natural mineral waters has a place in rational therapeutics (and this Society exists largely for the purpose of vindicating the affirmative) that place is surely occupied by the treatment of chronic diseases; and, among chronic diseases, the manifestations of gout to which I have referred certainly occupy the most prominent place. Almost all natural mineral waters are eulogised (not always, it must be admitted, from quarters which are wholly disinterested) for their powers in curing gout, and it behoves us, from time to time, to review these claims in the light of advances in knowledge both physiological and pathological. With this end in view I have prepared a table showing the amount per mille of common salt contained in many of the best known natural mineral waters which are used for drinking in the treatment of gout, in order that we see how far their anti-gouty claims are in consonance with the facts with which Widal's work has familiarised us.

With very few exceptions the quantities in these tables are taken from Dr. Huggard's book, (c) and they may therefore be regarded as representing in each case a fairly recent analysis.

GREAT BRITAIN.	*Per mille.*
Woodhall	19
Leamington	9·7
Harrogate	9·5
Cheltenham	7.0

EXPORTED PURGATIVE WATERS.	
Friedrichshall	7·9 per mille
Aesculap	2·9 ,,
Apenta	1·8 ,,
Hunyadi	1·7 ,,
Arabella	0·2 ,,

Parts per mille = grammes (15 grs.) per litre (35 fluid ounces).

To render parts per mille into grains per imperial gallon (8 pints), multiply by 70.

A glance at this table shows that the "anti-gouty" stations in England and Germany contain, as a rule, waters which are very much richer in chloride of sodium than the stations in France and Austria. It is, I think, reasonable to suppose that in the case of those waters which contain purgative salts to any appreciable extent, the excess of chloride of sodium is readily carried off by the bowels. This refers more especially to Carlsbad, Marienbad, Brides-les-Bains, Chatel-Guyon and, to some extent, it may also be held to apply to Cheltenham. In the case of sulphur waters, with the exception, of course, of those which happen to be strongly purgative, it is difficult to see in what way the extra amount of common salt is to be got rid of. Sulphuretted hydrogen exercises little or no influence upon the activities either of the skin or the bowels; so that we must suppose that if the chloride of sodium does not find an exit by the renal route, its ingestion in such waters may give rise to retention in the system, with consequences which have already been considered.

There are three stations in Germany, namely, Kissingen, Homburg and Wiesbaden, which have with some physicians, and not a few of the laity, in this country, a great reputation in the treatment of gout, So far as the ingestion of their waters is concerned their claims in this direction would seem to be very difficult to sustain Kissengen contains no less than 11.7 per mille; that is, roughly, two ounces per imperial gallon; Homburg, 9.8 per mille, or roughly 1¼ ounces per gallon; Wiesbaden, 6.8 per mille, or roughly one ounce per gallon. As estimated by the standard of what is harmless in conditions of ordinary health, these qualities are not perhaps very large. What we have to consider, however, is the effect of these quantities on a person who, from the very fact that he visits one of these places, is proclaiming that he is not in ordinary health; that he is, on the contrary, suffering from some manifestation of gout, and that, consequently, his kidneys may be regarded as potentially inadequate to the full discharge of their duties. Assuming that such a person drinks but a single litre a day of the natural mineral water, he thereby adds to the amount of ingested NaCl, at Kissengen by 11.7 grammes, or nearly double the amount (6.5 grammes) which Widal estimates as the ordinary quantity taken by a man in good health. At Homburg the increment would be 9.8 grammes; at Wiesbaden 6.8. The cure at these places lasts from a month to six weeks, so that the amount of additional common salt which is taken during that time must be very large, especially when we consider that no restriction is placed upon the ordinary dietetic consumption of the condiment. It is unnecessary to dwell upon the deleterious effects of this in the case of a person the permeability of whose kidneys is in any degree impaired by his gouty tendency. It should not, of course, be forgotten that the cure at these places is by no means confined to the drinking of the waters. Climate, baths, dietetic and general hygiene are all powerful and skilfully employed factors; but then all of these advantages can be obtained, in at least an equal degree, at stations whose waters are free from the drawbacks to which I have just called attention.

(c) "Handbook of Climatic Treatment" (Macmillan).

Of the stations in this country, Buxton and Bath contain the smallest quantity of the salt, the amount in both cases being insignificant. Both are therefore quite free from reproach in this respect. Among the sulphur water spas, Strathpeffer is the least, and Harrogate the most, open to objection from this point of view. The Strong Well at Strathpeffer contains no chloride of sodium at all, and the other wells contain rather less than about 4½ grains per gallon. At Harrogate the old Sulphur Well is that which is chiefly used for drinking purposes. It contains no less than 893.5 grains, or roughly two ounces per gallon. But then this well is, locally at any rate, credited with strongly purgative properties, and we are told that a large proportion of the surplus common salt is discharged by the bowels. In France those stations which include the drinking of the waters in their treatment of the various manifestations of the gouty diathesis are conspicuously poor in common salt. These stations have, moreover, much to offer in the matter of those climatic, balneary, and dietetic adjuncts to which I have already referred as constituting in the case of such places as Homburg, Kissengen and Wiesbaden, elements of "cure" which may be regarded as counterbalancing to some extent the evils of common salt in the waters.

It is unnecessary further to examine the details of this table in order to bring out the point that there are certain waters, notably in England and Germany, for which it is claimed that their ingestion is helpful to the goutily disposed, which, nevertheless, contain very considerable quantities of chloride of sodium. In view of the work which has been done by Widal, of which I have given a brief, and, I fear, a very inadequate *resume*, we are obliged to conclude that, other things being equal, chloride of sodium, so far from being advantageous to the gouty, is liable, even in small quantities, to be very much the reverse. I am aware that common salt is theoretically credited with diuretic properties, and although I am not concerned to deny to it such virtues in this direction as it may really possess, it is necessary to remember that the condition precedent to the exhibition of such virtues is the complete permeability of the kidneys, a condition which, in the case of the majority of the truly gouty, there is every reason to believe does not exist.

The main objects of the spa treatment of gout are the encouragement of metabolism and the promotion of excretion, and if there is any element in the treatment at a particular spa, such as the presence of chloride of sodium in the waters administered by the mouth, which is, in any degree, calculated to check the excretion of the nitrogenous matters by the renal route, then I say that he is a wise physician who directs his patients to avoid that spa and to seek in preference one whose waters can be relied upon under all circumstances to increase, and not to diminish the renal output.

One further observation seems pertinent in this connection. The reputation of some spas dates from the days when gout, and indeed most other maladies, were regarded as due to inactivity of the liver; when consequently, therapeutic skill was measured by the nicety displayed in graduating the amount of purgation, to the degree of hepatic obstinacy on the one hand and to the patient's powers of endurance on the other. I suggest that, having since those days revised our views of pathology, we should do well to bring our treatment, as far as possible into harmony with the teaching of to-day. This teaching may be briefly summarised by saying that gout is due to a fault of metabolism which leads to the retention, or perversion, or both, of nitrogenous waste matters, normally discharged by the urine. Whether or not the liver be responsible for the perversion, there can at least be no doubt that it is the kidneys which are responsible for the excretion. We cannot too often remind ourselves that the part played by the bowels in this matter, of the disposal of nitrogenous waste, is merely accessory. The real metabolic waste passes with the urine; it is only the ballast, the constituents of the food which are by their nature incapable of assimilation, which constitutes the fæces. In view of these facts it is surely to the spas such as Contrexéville, Vittel, Martigny, and more especially perhaps Evian, which increase the activities of the normal excretory channels, that we should advise our gouty patients, rather than to those which, like Carlsbad and Marienbad, occupy themselves mainly with stimulating an accessory emunctory. Still less should we continue to regard as suitable to such patients those spas whose waters, while acting perhaps as laxatives, nevertheless contain a considerable proportion of a salt which is potentially inimical to complete renal efficiency.

THE OUT-PATIENTS' ROOM.

CHILDREN'S HOSPITAL, PADDINGTON GREEN.

Coxa Vara.

By Arthur Edmunds, M.S., F.R.C.S.

Among the out-patients was a boy, æt. 3, suffering from coxa vara. The child learnt to walk in the usual way, but about six months before he came to the hospital he had an attack of measles, which had left him unable to stand. On examination it was apparent that this was not now due to muscular weakness, but to the fact that he was unable to bring his feet into the normal position. One foot could be internally rotated until the patella looked nearly forwards, being only about ten degrees out. On the other side, however, the patella could not be made to look directly forwards by about forty-five degrees. Mr. Edmunds pointed out that this was the extreme position of internal rotation, the feet being usually almost in a line with the heels touching. It was obvious that it was this diminution in the basis of support which was responsible for the child's inability to stand. This deficiency in internal rotation is, Mr Edmunds said, the cardinal symptom of curvature of the neck of the femur or coxa vara. This deformity usually consists of a double curve in the neck of the femur; one curve is in the coronal plane, the convexity of the curve being upwards, with the result that the angle between the neck and the shaft of the femur is increased, and the great trochanter is found above Nélaton's line. As the deformity is bilateral, shortening of the limb is not commonly apparent. The second curve is in the sagittal plane, with the convexity forwards, and it is this curve which produces the deficiency of internal rotation. Rotation at the hip joint is not actually limited, but the arc through which the trochanter rotates is translated backwards, so that the patella, although it can be made to look directly forwards, may be made to look almost directly backwards. The case in question exhibited the usual signs of the disease, the legs could be put behind the shoulders, and the child was distinctly rickety; there was a slight degree of knock knee. Slight degrees of curvatures of the neck of the femur, Mr. Edmunds remarked, are extremely common, and it is not difficult to see the cause. If a child with knock-knees be placed on its back with the patellæ looking directly forwards, the internal malleoli will be found separated by a considerable distance. If the child be now made to stand erect it will be seen that this separation of the malleoli is very much diminished, and if the child be made to sit on the edge of a table with its legs hanging over the edge, the separation will disappear entirely. It can readily be seen that this deformity is corrected by an external rotation at the hip joint. External rotation of the hip joint, therefore, is a deformity which compensates knock-knee, and the slight curvatures of the neck of the femur which accompany knock-knee are probably directly dependent on it. In a feeble rickety child also the tendency of the legs to fall into the everted position when the child lies on its back is also a factor in the production of the deformity. Given the curvature of a bone the relationship between opposing muscles is disturbed, and the deformity becomes exaggerated. The treatment of these cases, like other rickety deformities, falls into two heads—first, constitutional, and secondly, an attempt to remove the deformity. In children of this age there is no question of any bone operation, although plastic operations on the neck of the femur, subtrochanteric osteotomy and other measures may be necessary in cases where ossification is more complete. The method adopted in this case was simply to apply a splint on the outer side of the leg reaching from the upper border of the crest of the ilium to a point about four inches below the heel; opposite the hip joint a piece of wood is screwed to the splint projecting forwards at right angles for about four inches; the projecting portions are connected by a light elastic band, so that when the legs are firmly bound to the splint there is a slight but constant passive internal rotation at the hip joint, the long splint serves to keep the leg at rest, and also to afford a very wide surface for getting a grip upon the femur. It is always difficult, Mr. Edmunds said, to avoid exerting undue pressure on any one spot, especially when dealing with the delicate tissues of children, but by utilizing the whole limb as a *point d'appui* this difficulty is overcome. In a previous case which Mr. Edmunds demonstrated, the measures he had just explained had met with unqualified success.

Northumberland Sanatorium.

The sanatorium which has been erected at Barrasford under the auspices of the Newcastle and Northumberland Branch of the National Association for the Prevention of Consumption and other Forms of Tuberculosis, was formally opened a few days since by Lord Armstrong. For the occasion there was a large gathering, many who are interested in the movement travelling from the city by a special train. The Sanatorium is magnificently situated, some two or three miles to the north-east of Barrasford railway station; and the inspection of the buildings and the view which was obtained from them of miles and miles of moorland and woodland scenery, backed by the Hexhamshire hills, proved a source of pleasure to the visitors.

OPERATING THEATRES.

ST. THOMAS'S HOSPITAL.

Pancreatic Cyst Possessing Undue Mobility.—Mr. Battle operated on a married woman, æt. 27, who had been admitted for a tumour in the upper part of the abdomen. She stated that she had felt soreness in the pit of the stomach after straining three weeks before admission, and that she had noticed a lump in that part of the body for a fortnight. On examination, a rounded cystic tumour could be felt over the region of the stomach; it was about the size of the egg of a goose, painless, and not tender; it could be moved freely into the splenic region, across to the gall bladder, and downwards to the umbilicus. Its exact mode of origin was uncertain, and it gave no symptoms of pressure on other contents of the abdomen, nor was the function of any abdominal organ in any way deranged. The patient's general health was good. The tumour was removed through a median incision in the epigastric region. It was a single cyst situated in the gastro-hepatic omentum, and was adherent to the tail of the pancreas, some of which had to be peeled off it. Some of the attachments were rather vascular. The cyst, which was removed intact, was full of clear watery fluid which contained no reducing substance and no ferments. It was lined with columnar-celled epithelium. The layers of the gastro-hepatic omentum were united after the bed from which the cyst had been taken away was thoroughly dry, and the abdominal wall sutured in the usual manner. The chief interest in the case, Mr. Battle said, arose from the fact that the tumour was so extremely movable. Its situation before it was exposed by operation appeared to be between the stomach and the transverse colon, and it was somewhat of a surprise to find it situated above instead of below the stomach. The diagnosis before operation was necessarily uncertain; it resembled a hydatid cyst more than anything, whilst its excessive mobility rendered unlikely any suspicion that it had any connection with the pancreas. Some years ago, Mr. Battle remarked, he showed a large dermoid cyst to the Pathological Society, which had been removed by Mr. Sydney Jones from the wall of the small intestine, and in some ways the present tumour resembled that cyst, but the one he had just removed was situated higher up, and was more elastic.

Radical Cure of Umbilical Hernia.—The same surgeon operated on a very stout married woman, æt. 50, suffering from a reducible umbilical hernia. She had had nine children. She had used a truss for part of the time, but had had attacks of constipation, pain in the hernia, and vomiting; accompanying these attacks, for a time, also, the rupture, which was about the size of a duck's egg, had been irreducible. A transverse incision was made. The hernia was found to contain small gut. The sac was removed with some overlying skin. A first row of silk sutures was put in, uniting the divided peritoneum and edge of the opening in the linea alba, from below upwards; after this, an incision was made a third of an inch below the sutured line, and another at an equal distance above the same line. These incisions extended through the aponeurotic layer lying over the subperitoneal tissue; both lines extended beyond the end of the united opening, and were somewhat concave towards it; sutures were then passed through the uppermost divided edge and the lowest divided edges, and these were drawn together as the sutures were tied, thus forming a reinforcing layer for the first row. The skin wound was then closed with fish-gut sutures without drainage. The contents of the hernia were unusual, insomuch as they consisted entirely of small intestine, there being no omentum or large intestine present in the sac. Mr. Battle explained that the opening was closed after its edge had been trimmed with a knife from below upwards, making a mere transverse line, because the pull of the abdominal muscles was mainly lateral, and there was no drag on the sutures when put in in this manner. Before making the additional incisions it was, he thought, advisable to clear the surface of the fibrous tissue of fat so that material of the same character may be brought together and united. It was seldom that the two lines of suturings accurately corresponded, which he thought was a great advantage, and should be effected if possible, as it was a great thing to get either line of sutures strongly reinforced by an unweakened strip of the linea alba. In cases where it had been possible to do this operation, the results, he said, had been uniformly satisfactory.

TRANSACTIONS OF SOCIETIES.

CLINICAL SOCIETY OF LONDON.

Annual Meeting held Friday, May 24th, 1907.

The President, Mr. H. H. **Clutton**, in the Chair.

The reports of the Council and Treasurer were presented and adopted. With the conclusion of the present session the Clinical Society becomes merged in the new Royal Society of Medicine.

TWO CASES OF PROLONGED PYREXIA.

Dr. F. **de Havilland Hall** read the notes of two cases of prolonged pyrexia of hectic type. The first was that of a man, æt. 44, with pulmonary tuberculosis and enlarged glands; the second was that of a man, æt. 21, with ulcerative endocarditis. Dr. Hall pointed out that in practice cases of prolonged pyrexia were more commonly due to tuberculosis and malignant endocarditis than to any other two conditions. In arriving at a diagnosis family history might be of a certain assistance, as the occurrence of several cases of tuberculosis among the immediate relations of the patient should awaken suspicion. On the other hand a rheumatic family history should suggest the possibility of a rheumatic endocarditis. The past history of the patient would often yield valuable information, as for instance attacks of hæmoptysis, pleurisy, fistula in ano, enlarged glands, etc., might lead one to suspect tuberculosis. The history of pneumonia was of equivocal value. Pulmonary tuberculosis might supervene upon lobar pneumonia, especially of the apex, but against this was to be placed the fact that pneumonia was one of the most common antecedent conditions of ulcerative endocarditis. The history of acute rheumatism followed by cardiac trouble should incline the scale strongly in favour of ulcerative endocarditis. The comparative rarity of the association of valvular disease and especially mitral stenosis with pulmonary tuberculosis was insisted on. Stress was laid upon the importance of several examinations of the sputum, one or two negative results not being sufficient to exclude tuberculosis.

Dr. **Sidney Phillips** suggested the addition of ulcerative aortitis and ulcerative colitis to the list of causes given by Dr. Hall. He did not think that the absence of bacilli from the sputum excluded tuberculosis. He objected to the term hectic pyrexia, as in hectic fever any form of temperature chart might be present.

Dr. T. **Walter Carr** commented on the difficulty of diagnosing infective endocarditis, particularly in the absence of any evidence of valve lesions. He related the case of a man, aged 67, who had nothing but chronic pyrexia with rigors till a sudden attack of hemiplegia supervened and caused death in a few days. At the autopsy was found a large mass on one flap of the mitral valve.

Dr. C. R. **Box** referred to the pyrexial crises that might arise in chronic posterior basic meningitis.

Dr. **Glover** said that chronic pyrexia was sometimes of rheumatic origin.

Dr. **de Havilland Hall**, in reply, said that he used the term hectic pyrexia to included both intermittent and remittent pyrexia.

Dr. A. M. **Gossage** read a paper on

HEART BLOCK.

After pointing out that conductivity might be affected separately from the other functions of cardiac muscle, he explained that depression of conductivity showed itself chiefly in the muscle fibres that connect auricles and ventricles. Depression of conductivity was illustrated by tracings showing a lengthening of the normal interval between the contractions of the auricles and the ventricles; the dropping out of ventricular beats was shown when conductivity was further depressed, *e.g.* by digitalis or the action of the vagus. Tracings were exhibited where there were three auricular beats to every two ventricular, two auricular to one ventricular, and three auricular to one ventricular. In the last two cases the patients exhibited the Stokes-Adams Syndrome. The nervous attacks of this Syndrome were shown to be preceded and accompanied by a cessation of ventricular contractions over a considerable period. Wenckebach had suggested the possibility of a block occurring between the veins and the auricles, and a tracing was shown where two successive ventricular beats had apparently been dropped, a circumstance which could be explained by a block between auricle and ventricle for the first beat and between vein and auricle for the second.

A paper by Dr. F. W. Price on

FOREIGN BODIES IN THE BRONCHI

was taken as read.

Votes of thanks to the officers of the society terminated the proceedings.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Clinical Meeting held in the Royal Hospital for Sick Children on May 15th, 1907.

Dr. **Craig** in the Chair.

Dr. **Melville Dunlop** showed: (1) a case of infantile paralysis in which the abdominal muscles of one side were affected. Whenever the child cries or strains, the right half of the abdomen balloons out in a remarkable manner. The muscles do not re-act to faradism. Paralysis of the abdominal muscles is an extremely rare event in anterior poliomyelitis. (2) A baby with a rickety head, in which craniotabes was unusually well marked, the whole of the occipital and posterior parietal regions being soft and membranous. (3) A child with a peculiar bilateral scarred condition of the skin over the sacrum, the result of an attack of herpes. (4) A case of cretinism after fourteen years' treatment.

Mr. H. J. **Stiles** showed (1) a baby after operation for a large hydronephrotic cyst. (2) A boy after nephrotomy for advanced tubercular pyonephrosis. (3) A child after resection of the ilio-cæcal junction and part of the ascending colon for fæcal fistula following suppurative appendicitis. (4) Two cases of removal of the diaphyses of the tibia for tuberculous disease. In subperiosteal removal of the diaphyses the epiphysial line remained intact, and in the two children shown the tibia had been completely renewed. X-ray photographs showing the condition before operation, and at the present time, were also exhibited. (5) A baby with a large encephalo-cystocele (partial exencephalus). The whole brain, practically, was extended from the deficient cranium, and covered only with skin. In cases of encephalocele, meningocele, and spina-bifida, the dura mater was usually absent. The dura plays a more important part in the formation of bone than the pericranium, and the absence of the dura apparently has to do with the bony defect which is the ultimate cause of these malformations.

Dr. J. S. **Fowler** showed (1) a child who at the tenth month had suffered from unilateral convulsions, beginning in the face and passing down to the arm and leg. There was a distinct syphilitic family history. Under iodide the convulsions were speedily checked, but as there was reason to suppose that in such cases some syphilitic cortical lesion was present, the ultimate prognosis was not good; probably some mental defect would result. (2) A typical case of posterior basic meningitis, to contrast the appearances with those of the epidemic cerebro-spinal form of the disease.

Dr. W. B. **Drummond** showed a Jewish child suffering from amaurotic family idiocy. It was the third member of the family who had been so affected. From being a healthy, normally bright infant at eight months, the child was now, at fourteen months, apathetic, almost blind, and displayed the characteristic fundal changes.

Dr. J. W. **Simpson** showed (1) a case of rickets with large posterior beads of the ribs. Posterior beads differed from the common anterior form in being due to calcus from periostic fracture. (2) A child, æt. 2¼, with leukæmia. The points to be noted were, first, the enormous spleen, which filled almost the whole abdomen, and secondly, the fact that the disease was of the spleno-medullary type, which was at this age excessively uncommon.

Mr. E. **Scott Carmichael** showed a case of streptococcus peritonitis which had recovered after laparotomy. The patient was a Mongolian imbecile.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

Meeting held at Leeds, Friday, May 10th, 1907.

Dr. E. O. **Croft** (Leeds), President, in the Chair.

The President showed a microscopical specimen from a case of "Primary Carcinoma of the Urethra," removed from a married woman, æt. 37, who had complained of painful micturition with soreness and irritation for several months. The growth occupied the posterior lip of the meatus urinarius, and extended three-quarters of an inch down the urethra, destroying the urethra-vaginal septum. Enlarged glands were present in both groins. Complete removal was impossible.

Dr. **Hellier** (Leeds) exhibited a specimen of "Tubal Mole" removed from a multiparous woman, æt. 30, who had been married four years. Menstruation ceased on February 12th, and on April 7th she was seized with severe abdominal pain, accompanied by a red discharge. The uterus was somewhat enlarged, and there was a swelling in the left posterior quadrant of the pelvis. Abdominal section was performed on April 11th, and free dark blood was found in the peritoneal cavity. The left Fallopian tube measured 4 in. by 2 in., and was occupied by blood clot, in which chorionic villi were found.

The **President** (Dr. Croft) introduced a discussion on

THE TREATMENT OF ALBUMINURIA AND ECLAMPSIA OF PREGNANCY,

an abstract of which will be found on page 589.

Dr. J. B. **Hellier** (Leeds) advocated all measures directed toward the elimination of the toxine. He used saline injection and transfusion. He was in favour of the interruption of pregnancy as removing the exciting cause of the toxæmia, but did not believe in too rapid dilatation of the cervix and evacuation of the uterus.

Dr. **Lloyd Roberts** (Manchester) discussed the treatment of albuminuria of pregnancy, and laid stress on rest in bed, warmth, and dietetic measures, especially milk. He advocated intestinal antiseptics—*e.g.*, calomel, or grey powder, and saline purgatives, with the object of preventing auto-intoxication from the alimentary canal.

He would encourage the onset of labour when in spite of prolonged treatment the albuminuria increased or profound symptoms supervened. Coma and intermittent cardiac action he regarded as indications for the employment of more prompt measures.

Dr. **Stookes** (Liverpool) thought there was no distinct advance in the treatment of eclampsia. He referred to Ramsbotham's obstetric table from 1828 to 1850, including 48,776 cases with 220 deaths, a mortality of 4.5 per 1,000, which is rather less than that of England and Wales at present. In this table are 43 cases of convulsions before and after delivery (1.1 per 1,000), with only three deaths.

Now at the Liverpool Lying-in Hospital, between the years of 1886 and 1905, out of 3,818 admissions there had been 52 cases of uræmia and eclampsia, and out of these 22 have died, or 42 per cent. The incidence was the more interesting as 39 of the 52 cases have occurred during the last ten years.

Dr. **Stookes** regarded the prevention of eclampsia as far more important than its cure, and attributed the increase in this disease to increase in intestinal affections. He thought food played a very important *rôle* in the causation of the latter. For the pregnant woman he advocated routine and careful attention to the cleansing of the alimentary canal.

He believed in the free use of gastric and rectal lavage and saline injections into the subcutaneous tissues. He objected to the introduction of labour in the pre-eclamptic condition. He had not found thyroid to be of much value. In the eclamptic stage he preferred to treat symptoms, and allow labour to come on, if possible, spontaneously.

Dr. **Walter** (Manchester), having discussed the treatment of albuminuria of pregnancy, said that in the treatment of eclampsia he had found morphia useful. In one case, in which 10 fits had occurred during the night, the patient was admitted into hospital, morphia gr. ⅙ was administered. The patient slept 12 hours, no more fits occurred. Aperients, salines, and diaphoretics were also given. On the tenth day all albumen had disappeared, and the patient returned home. Two days later she was re-admitted in labour, and delivered by forceps of a living child, without any recurrence of albumen or fits.

In most cases of eclampsia he advocated emptying the uterus without delay, commencing, if necessary, with Hegar's dilators, then Champetier de Ribes' bag, and, when possible, using forceps rather than version. If Morphia gr. ¼ was given first, he believed less chloroform was needed. Saline injections, purgatives, and diaphoretics were essential. He had seen but very temporary benefit from venesection, and had not tried incision of the cervix or vaginal Cæsarian section.

Dr. **Croft** replied.

LIVERPOOL MEDICAL INSTITUTION.

Meeting held Thursday, May 2nd, 1907.

The President, Mr. **Frank T. Paul**, F.R.C.S., in the Chair.

NUCLEO-ALBUMINURIA.

Dr. T. R. **Bradshaw** related the case of a lad, æt. 17, in which nucleo-albumin in large amount was mistaken for myelopathic albumose. The patient when seen was greatly emaciated and exhausted, and died in about a week. The urine contained about one per mille of a proteid body which gave a turbidity when the urine was gently warmed with acetic acid, and which coagulated with hydrochloric acid. There was a remarkable deformity of the sacrum and tenderness over the upper ribs. The *post-mortem* showed extensive matting of the intestines from tubercular peritonitis, marked lordosis and inflamed glands under the pectorals. The bone substance was normal. After removing the urinary salts by dialysis the proteid was found to be precipitated by a trace of acetic acid, and gave the other reactions of nucleo-albumin. The significance of nucleo-albuminuria was not understood.

Dr. **Hubert Armstrong** remarked that nucleo-albumin occurred in the urine of children with some frequency. Precipitating with acetic acid in either hot or cold solutions, nucleo-albumin was occasionally mistaken for serum-albumin when the acid was not added to the urine until after boiling. In none of the cases he had seen could he attach any clinical significance to the presence of nucleo-albuminuria.

INTRA-TRACHEAL INJECTIONS OF IZAL.

Mr. **Colin Campbell** and Dr. **Masson** described a case of bronchiectasis, or rather of bronchiolectasis, and exhibited the patient, a male, æt. 38. When two years of age he had had a severe attack of German measles with pneumonia, and when twelve years old another attack of pneumonia. From the first attack he had never been free from cough. He came under Dr. Masson's care in 1901, and was then expectorating about a pint of glairy mucus twice in the twenty-four hours. The physical signs were practically confined to the lower lobe of the left lung. There was marked clubbing of the fingers, typical odour and much emaciation. For four years his condition grew worse in spite of all treatment, and the patient spent his winters in bed.

At the suggestion of Dr. Dreschfeld, who saw the patient in consultation with Dr. Masson, the patient was placed in Mr. Campbell's charge for intra-tracheal treatment. This treatment was commenced in May, 1906, and continued until December. About 2½ oz. of a 9 per cent. solution of Izal in glycerine was administered daily, and by means of Mr. Campbell's revolving chair the medicament was sent directly into the diseased part. According to the patient's calculation 40 lbs. by weight of Izal were used. While not liking the word "cure," Mr. Campbell claimed that it looked as if the patient had been cured. He had spent the last winter at work on his farm instead of in bed, had gained 16 lbs. in weight without any attempt at fattening, the clubbing of the fingers had disappeared, there was no cough and no expectoration.

At the request of the President, Sir James Barr examined the patient and reported that he agreed with Mr. Campbell's estimate of the effect of the treatment.

NOTES OF A CASE OF CEREBRO-SPINAL MENINGITIS—ISOLATION OF THE ORGANISM FROM THE CEREBRO-SPINAL FLUID-PREPARATION AND ADMINISTRATION OF A VACCINE—RECOVERY OF PATIENT.

Dr. **Claude Rundle** and Dr. **W. Stenhouse Williams** gave a full account of this case. The opsonic index was first determined on the 23rd day of the disease, and the vaccine first administered on the 27th day, and for the fifth and last on the 31st day. The coccus was obtained in pure culture from the cerebro-spinal dyes on Loffler's blood serum. It stained with the usual aniline dyes: Gram negative. Morphology: Cocci, diplococci, tetrads, adjacent surfaces of diplococci flattened, great in variety and size; no tendency to chain formation in liquid media. Anærobic cultures at 37 C. negative and ærobic cultures at 20 C. negative. The behaviour of the organism was compared with that of three strains from Glasgow and one from Belfast in ascitic fluid, carbohydrates cultures at 37 C.

The agglutination reactions were fully described. The authors did not, of course, claim that the recovery of a single case was to be regarded as proof of the efficacy of the vaccine, but recovery after the patient had been almost *in extremis*, and dating from the first administration of the vaccine was at least encouraging.

CALCULUS OF THE KIDNEY AND URETER AND SOME KIDNEY TUMOURS.

RENAL AND URETERAL CALCULI AND SOME KIDNEY TUMOURS.

Mr. **W. Thelwall Thomas** read a paper on the above subject. The stone cases formed a series of 28 operated on since 1904, a large proportion since 1903, when the X-rays proved of great service in locating even tiny calculi. All the radiographs had been taken by Mr. Thurston Holland.

The most common symptom had been pain in the back of a dull aching character. This occurred in 17 cases, typical renal colic only occurring in 9; colic was associated with hæmaturia and pyuria in 3, and with hæmaturia alone and pyuria alone in 1 case each. In 7 cases pain in the back was associated with pyuria, in 3 with hæmaturia and pyuria, and in 2 with hæmaturia. Hæmaturia was the only sign in 3 cases, and pyuria in 13. The cystiscope was of service in some cases by enabling ureteritis to be diagnosed; but the important confirmatory evidence was supplied by the radiographs.

The prone position was adopted during operation in all cases, and Edebohl's cushion rendered great assistance. Evisceration of the kidney was resorted to when possible and the pedicle clamped before incising the kidney substance. The kidney had to be removed in three cases on account of hæmorrhage. Death occurred in 1 case of nephrectomy for tubercle and stone, and in another from pneumonia after the wound had healed. Four cases of ureteral calculi were discussed, and a combined ilio-perineal or ilio-vaginal operation described. Seven cases of renal tumour were related, six of hypernephroma hæmaturia being the chief symptoms in all. All the tumours were removed by the lumbar incision. In one case prolonged anteriorly, the tumour weighing 3 lbs. Four of the hypernephroma patients were still quite well.

In cases in which the kidney could not be made out by palpation, cystoscopic examination enabled the affected side to be decided upon.

A full epitome of the calculus cases had been compiled by Dr. R. E. Kelly; this was circulated amongst the members and the calculi and radiographs exhibited.

Mr. **G. G. Hamilton** pointed out that after all a calculus of nephritic origin was a "symptom" just as was a gall-stone, and depended on the state of the lining membrane and the presence of micro-organisms. A prone position similar to that advocated by Edebohl had been found the best for many years at the Royal Infirmary. The difficulty in the interpretation of X-ray shadows arose from the occurrence of calcareous plates on arteries and of calcareous glands. In one of his cases the passage of a ureteral catheter, which threw a shadow, cleared up the diagnosis.

Mr. **C. Thurstan Holland** drew attention to the difficulties in the X-ray diagnosis of kidney stones, with especial reference to the shadows caused by calcareous glands, pointing out that such shadows might occur in any part of the stone area. At the present time, however, the X-ray appearances are so valuable that it was unjustifiable, given any symptom which raised the question of stone, to continue medical or surgical treatment without having a complete and satisfactory X-ray examination of the whole urinary tract, further treatment being based upon that examination.

Dr. **J. Hill Abram** said that success could be obtained in some cases by the free drinking of certain waters, although he agreed with Mr. Thomas that the solvent action was practically nil, at any rate, in the body. He had also seen expulsion of the calculus under the belladonna treatment recommended by Dr. Murray (senior), of Newcastle. He was struck with the large proportion of Mr. Thomas' cases in which pain in the back was the only symptom; he could add two similar cases from his own experience, one of exceptional interest, inasmuch as jaundice, had been present on one occasion. These cases strongly emphasised the value and importance of X-ray examination in all cases of persistent lumbar pain.

The following gentlemen also discussed the paper:—The President, Mr. Rushton Parker, Mr. R. W. Murray, Mr. K. W. Monsarratt, Mr. R. A. Bickersteth, Sir James Barr (who remarked that stones ought not to be allowed to form at all or to recur after removal), and Dr. E. T. Davies.

North Dublin Medical Supplies.

Mr. Denis Lynch explained at a recent meeting of North Dublin Guardians that the Local Government Board had received in a sympathetic manner the points made by the deputation of Guardians which recently waited on the Board in connection with the question of medical and surgical appliances for last year. The Local Government Board accepted the contract for last year, and committed themselves to the expression that they were ready in future to make concessions to local firms, even to the extent of 5 per cent. In connection with the contract of last year, they were allowed the full amount of the recoupment—£2,500. Mr. Lynch concluded by moving a resolution—which was seconded by Mr. M'Gough and passed—that the Guardian's reason for accepting the contract for surgical appliances from Messrs. Smith and Sheppard this year at 36½ per cent. off, as against 37½ tendered by a Liverpool firm, was the great convenience of the first-named contractors residing in Dublin.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, May 26th, 1907.

Treatment of Phthisis.

For a long time back, a comparison has been made between the waste of phosphoric acid at the outset of tuberculosis, and the final calcification of tubercles that get well. Just as the farmer supplies in an artificial manner the loss that a crop causes to the ground, an attempt has been made to cover, by phosphates given in abundance, the losses of phosphorus in tuberculous patients.

M. Ferrier, who read an interesting paper on this subject at a recent Congress, said that the patient not only lost phosphoric acid, but also lime.

Frequently, phosphate of lime and more especially glycero-phosphate of lime, has been given in phthisis, but the question is, not to take lime, but to assimilate it; and all the lime salts are not equally good. Sulphate of lime, acidified phosphates such as lacto-phosphate, monocalcic phosphate which is acid, increase the elimination of lime. On the other hand, the insoluble salts, as carbonate, phosphate (tricalcic), are easily assimilated and retained.

In all cases it is necessary to prescribe a rather severe regimen as in patients taking carbonate of lime; decalcification may be produced by accidental causes (absorption of acids entering into the food, and particularly of citric acid, of oranges and lemons, and, above all, gastric fermentation provoked by ill-feeding).

The patient should be forbidden the use of wine, beer, cider, liqueurs, or, in a word, any drink containing alcohol; salad, vinegar, oranges, lemons, lemonade, or butter, which is liable to produce acid fermentation in the stomach.

The patient should be allowed bread (not more than 10 ozs. a day), potatoes, carrots, split peas, macaroni, milk. The only drink should be St. Galmier water, or some other spring containing lime. If the waters contain gas, the bottle should be left uncorked, so that the carbonic acid gas escapes.

The *menu* might be as follows for each meal: At 6 o'clock in the morning, a glass of mineral water to insure the evacuation of the stomach in case there remained undigested food from the evening before.

At 7 o'clock, two eggs with 2 ozs. of bread, followed by a wafer, the composition of which is given below.

At 11 o'clock, a glass of mineral water.

At 12, dinner composed of lean meat, eggs, fish, except mackerel, herring, or salmon, sweetbread, kidneys, ham (unsmoked), a little vegetable, and 3 ozs. of bread. A wafer.

At 6 o'clock, a glass of mineral water.

At 7, potage, meat, eggs, a little vegetable, and, for dessert, cooked fruit, a little bread and a wafer.

The wafers prescribed by M. Ferrier are:—

Carbonate of lime, gr. 10.
Tribasic phosphate of lime, gr. 4.
Chloride of sodium, gr. 3.
Calcined magnesium, gr. 3.

In children, the dose of salts of lime is 6 gr. daily for the first year, and increased by 1 gr. for each year above that age.

Patients who possess a normal digestion, says M. Ferrier, improve rapidly under the above treatment. But, besides these wafers, small doses of chloride of calcium might be given twice a day in solution (10 grs. twice a day).

This treatment will be associated with other hygienic prescriptions such as ventilation, cutaneous frictions, &c. But it is quite sufficient in the initial stage of the malady. Later, it can be concurrently employed with other treatment necessitated by the condition of the patient.

M. Ferrier has published in favour of his method several interesting cases, and his statements have been confirmed by Sergent and Renon.

For the last eighteen months, says M. Sergent, I have submitted to the treatment of recalcification a large number of phthisical patients, and I affirm that the scepticism with which I received, at the beginning, the method proposed by M. Ferrier, vanished rapidly before the facts. From the very first days of the treatment, the digestive functions, disturbed previously by the classical and frequently ill-tolerated over-feeding, were restored, the appetite returned, and the patients gained strength; progressively the general condition improved, while the local sign of congestion disappeared. Naturally this method does not guarantee a cure by itself, but it certainly contributes to the cure of phthisical patients on the condition that it is carried out to the letter.

GERMANY.

Berlin, May 26th, 1907.

At the Medizinische Gesellschaft, Hr. Lohenstein reported a case of

Paraffin Calculus of the Bladder.

The patient was a young workman, æt. 23, who had suffered severe bladder pain for eighteen weeks, and had been treated unsuccessfully so far. On cystoscopic examination, in addition to signs of subacute inflammation of the bladder there was an ovoid yellow foreign body with a smooth surface; it was not attached to the bladder, but on account of its low specific gravity it lay close to the bladder wall. It could not be expressed by pressure from without. It could only therefore be a waxy mass, and the patient, on being pressed stated that on account of itching along the urethra he had passed in a pencil made from paraffin. It was remarkable that although the mass had been in the bladder five months, there was not the least incrustation on it. By repeatedly injecting benzine that could be retained in the bladder for forty minutes at a time, the foreign body was dissolved and discharged in the course of a couple of days. The paraffin was again obtained from the solution by distillation.

Hr. F. Krause showed (1) a patient who had paralysis of all four extremities, the result of an inconsiderable fall on to his back. There was no sign of injury along the spinal column. There must have been extravasation of blood into the spinal cavity. The paralysis did not improve until after the lapse of three months. Now, nine months after, the patient could walk with two sticks; the gait was spastic. (2) A boy who had as early as 1900 been treated for tuberculous spondylitis with a plaster jacket, there being no sign of paralysis. In 1901 in connection with an attack of varicella the condition became much worse, so that within a short period there was complete paraplegia of the lower half of the body. As treatment by extension was useless an operation was performed. Several spinous processes were resected, a granulation mass was found and several vertebral bodies completely destroyed. From here an abscess proceeded into the posterior mediastinum, which was opened from behind and drained. There was absence, therefore, of several of the bodies, and spinous processes, and the parts were retained in position only by the lateral processes. They were sufficient, however, for support. With very careful after-treatment, the wounds healed perfectly, and five months afterwards the first sign of returning movement in the paralysed parts was observed and the boy gradually learned to walk with sticks.

Hr. Westenhœffer made a communication on the

Nature of Tumours with Special Reference to Cancer.

He said there was no prospect of solving the question by histological and morphological investigations; that any further advance could only be expected from experimental and biological inquiries.

Tumours were on the one hand independent formations, on the other they lived in symbiosis with the organism. That was parasitism, a relation common to all tumours.

For the scientist and in the general consideration of the essential nature of tumours, the histological structure was not of much importance. For the sake of simplicity the speaker had turned to the consideration of carcinoma that showed its parasitic character by unlimited growth as well as by its tendency to develope metastases.

How it was possible that cells of the organism suddenly took on a parasitic character was hitherto an unsolved problem. The cells had not by this lost their character, as was shown by their limitless growth, but their specific character, for instance, their capacity for secreting, etc. A cell had not thereby become an embryonic cell, it had indeed the enormous power of development of that cell, but it lay in the nature of the embryonic cell to develope in harmony with the needs of the organism. The characteristic of the tumour cell lay in the ontogenetic development much further back, it corresponded rather to the type of the primal cell (Urzelle).

To prove the truth of this theory he had made various biological experiments; on the one hand he had proved that the juice of cancer digested both animal and vegetable albumen., and on the other the serum of animals that had been treated with carcinoma showed changes in the sense of complementary aversion, in the sense of averting.

It was true that liver cells could digest albumen, but only that of foreign bodies. Carcinoma cells, on the contrary, could digest their own body albumen.

Further investigations would follow. The immediate cause for a cell of the organism to lose its own specific character and take on one of growth he considered to lie in the action of a chronic irritation, and as an illustration he adduced the development of cadaveric tubercle.

AUSTRIA.

Vienna, May 26th, 1907.

Pulmonary Gangrene.

At the Gesellschaft Lotheissen demonstrated two patients on whom he had operated for gangrene of the lung. These were the last two of nineteen within the last four years with a mortality of 40 per cent., which is lower than the late Lenhartz, who had a mortality of 60 per cent. None of the deaths were due to the operation.

Ozone in Surgery.

Gleich gave an account of his practice with ozone in surgical operations. The idea is not new, but the application of the gas to the wound has always been the difficulty. His first experiments were conducted with oxygen and ozone mixed, which he blew into the wound from a condensing cylinder. He is still hopeful with a high tension current to regulate the quantity and make the treatment practicable by means of electricity. He finds the gas a powerful antiseptic in the dressing of wounds.

Peritoneal Pseudo-Ligaments.

Lorenz demonstrated the fallacy of his opponents in the belief that pseudo-ligaments did not exist. The preparation which he exhibited was taken from a patient who some time previously had been operated on by a colleague for appendicitis. The false ligament passed over the ileocal valve, which was firmly attached to the mesentery, which made a circle of 180 degrees around the bowel, quite strangulating it. Within the last three years he has operated for three of these cases after appendicitis. In all three the appendix had been misplaced; that probably led to the operation being necessary. Where simple appendicitis exists without displacement he is of opinion that no pseudo-ligaments will arise, and that early appendictomy should be performed to avert this subsequent accident.

Therapy of Puerperal Diseases.

Latzko next read a long paper to the members on the latest treatment of puerperal inflammations, such as parametritis, metastatic abscesses, etc. The diseases usually leading to these morbid changes are bacterial and are comprehended under endometritis, metrophlebitis and peritonitis, which have common ætiology in being microgenic and to which the modern operation is applicable. The so-called radical operation or extirpation of the uterus may be excluded, although it is recognised as the most effectual, but it is usually considered unnecessary, or the case is received too late. The total number received into his own ward was 470 puerperal cases with 112 deaths, a little under a fourth of the total number. Among the total were 117 septic abortions, 42 of them with a temperature of 38.5 on reception = 101·5 Fahr. followed by parametritis, peritonitis and death. There is another class of high fever cases in the number with only 30 per cent. of deaths, which causes one to pause before pronouncing the "indicatio vitalis" which decides the operation according to Sippel's dictum. In his own ward the rule is, if a patient maintains a temperature two days at 39° or 40° centigrade or over this for 48 hours without improvement, the case is operated on without any further formality. Operate early in these cases as in appendicitis. The aim of the surgeon is to limit or destroy the source of the puerperal pyæmia by tying the veins and cutting off the septic supply. The danger from medial laparotomy in extra peritoneal operations is very small if ordinary care be exercised. The tying of the veins is best accomplished by Bumm's method. The separation of the artery and vein is not always an easy matter when phlebitis is present, particularly in the hypogastric and spermatic. The tying of the artery should be carefully avoided as the pus of the ligature cannot be prevented from entering the circulation. Where thrombo-phlebitis of the vaginal plexus is present the hypogastric veins should be tied and as many removed as possible, as the purulent matter can be easily cleared by the vagina. The arteries and uterus should be carefully observed, while the veins should be carefully emptied and the spongy parts tamponned. Never delay operating with high temperature rigors with general disturbance, as many lives are lost by waiting. In peritonitis, laparotomy with washing the cavity with salt and water is better than colpotomy as formerly practised.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

Lunacy and the Law.—A case which was tried at the High Court of Justiciary on May 20th illustrates the curious relationship of insanity in criminal procedures. In what was referred to some weeks ago as the New Cumnock poisoning case, the prisoner, though desirous of standing his trial for murder, and anxious to rebuke the theory of the prosecution that he was insane, was found to be of unsound mind and therefore incapable of giving instructions for his defence, and was accordingly ordered to be detained during His Majesty's pleasure, though the actual question of his guilt was never settled by the jury. This present case is in some respects the exact converse of the preceding. Thomas M., in 1899, was arrested on the charge of having shot his aunt, and at the time he was found to be incapable of instructing his defence, being of unsound mind. As a matter of fact, Dr. Clouston and other experts who examined him at the time found that he was suffering from insane delusions which were of a nature to lead him to commit the crime in question. He was accordingly confined in an asylum, and under proper treatment he has now recovered his reason and was discharged a sane man a month ago. According to practice he was rearrested and the crime inquired into again. Evidence was led on Monday as to the circumstances under which the murder was committed, and medical testimony was given that the prisoner was insane at the time, and was now recovered and perfectly sane. The Solicitor-General, in addressing the jury, said this was a very peculiar and unusual case. After the evidence led it was obviously impossible for him to ask them to find the prisoner guilty. It had become the duty of the Crown authorities not to let the accused lie down under the charge of murder but to place the facts before a jury so that they might pronounce a verdict absolving him from that charge. He said absolving, because if a jury called upon to investigate a charge of murder thought that the prisoner was insane when the act was committed their first duty was to find him insane, and their second to find him not guilty on account of his insanity. The Lord Justice Clerk directed the jury to deal first with the act which the accused had committed, and then with the question of insanity. The jury found the prisoner not guilty on the ground that he was insane at the time he committed the offence. The Judge then made the usual order, that the prisoner be kept in confinement "until His Majesty's pleasure be known." The next step will be to apply to the Secretary for Scotland for his release on the ground that he has recovered from his insanity.

The two cases are on all-fours in this respect, that the Crown, not the defence, pressed the question of insanity, and to this extent defended the prisoner against a verdict of murder. In the New Cumnock case we had, as the result, the verdict that the patient was insane, and no decision as to whether he had committed the crime alleged; and the sentence of detention in an asylum. In this case the same thing occurred, and after a lapse of eight years, on the recovery of the prisoner, his guilt is again inquired into, and he, admittedly now sane, is sentenced to be detained because he was insane when he committed the act. Presumably his second detention is merely a formality, and will be of short duration, but the curious topsy-turvy state of matters the case reveals suggests that criminal procedure, in cases of insanity, requires some revision.

Cerebro-spinal Meningitis.—In Edinburgh and Leith the epidemic of this disease is showing no signs of increase, though a few cases occur every week. For the week ending May 18th two cases were notified in Edinburgh; five of the cases in the city hospital died, and sixteen remained under observation. In Leith during the same period four cases were notified. Although the outbreak had not been serious numerically, the mortality had been very high. Probably the death-rate is not much under 90 per cent. of those affected.

Galashiels Consumption Sanatorium.—This sanatorium was opened for the reception of patients on May 20th. It accommodates six patients, and has been erected by the efforts of the local branch of the National Association for the Prevention of Consumption, as the outcome of a lecture delivered in the town by Dr. R. W. Philip, Edinburgh. It is stated that phthisis is unusually prevalent in Galashiels, and this fact has enabled the committee to obtain funds enough to have erected the sanatorium within a comparatively short space of time.

BELFAST.

Cerebro-Spinal Meningitis.—Last week the number of cases of this disease reported was rather less than in recent weeks, being 24 as compared with 29 the week before. The number of deaths was 21, but the more recent cases show a tendency to be milder than the earlier ones. The total number of cases in Belfast is now 445, and the total deaths registered 316. A child died in Lurgan Union Fever Hospital last week from cerebro-spinal meningitis, making the third death in this institution.

County Antrim Infirmary, Lisburn.—The annual report of this hospital has just been issued, and shows an increasing amount of work. Dr. St. George reports having had under his care 376 intern and 454 extern patients. A charge of one shilling is now made in the extern department for all except workers in public works which make an annual collection for the hospital funds. The daily average of patients in the hospital was 36, and 85 accident cases were admitted to the wards. The operations numbered 149. A complete X-ray of apparatus had been presented to the hospital by the Barbour family of Lisburn, to whose generosity much is already owed.

The Health Commission.—The Commission has adjourned till July 15th, when it is hoped that a final series of sittings will conclude the hearing of evidence. Before adjourning they heard evidence from Dr. John McCaw, senior physician to the Belfast Hospital for Sick Children. He dealt with the infantile death rate, which he said was 144 per 1,000 in 1906, and was much too high, though probably 80 per 1,000 was inevitable in a manufacturing city like Belfast. The diarrhœa diseases and rickets were accountable for 50 per cent. of the infantile mortality. The mothers went to work and left their infants to the care of old women, who undertook the duty for a small payment, out of which they bought the food, probably skim milk at a penny a pint. This milk was exposed for sale in small shops in a most objectionable way, and he thought the Corporation should have control over it. Deaths from overlying were common, specially on Saturday nights, and the witness thought that where the mother was proved to have been drunk she should be prosecuted. He joined with previous medical witnesses in advocating a crusade of cleanliness.

LETTERS TO THE EDITOR.

THE ALCOHOL MANIFESTO.

To the Editor of the Medical Press and Circular.

Sir,—May I call attention to a statement made by your correspondent, Dr. Churchill, relating to the consumption of alcohol at Guy's Hospital in 1905? The sentence in his letter of the 15th inst.: "Of this amount the resident staff no doubt help to consume a fair amount of alcoholic drinks in each hospital," might lead the reader to suppose that in the figures quoted are included the "alcoholic drinks" of the resident staff. As a matter of fact, the figures relate to alcohol supplied to patients only, the alcohol for the resident staff being included in the separate items, "Board of Resident Medical Officers" and "Board of Nursing Staff."—I am, Sir, yours truly,

E. C. Perry, Superintendent.

Guy's Hospital, London, May 23rd, 1907.

THE EDALJI CASE.

To the Editor of the Medical Press and Circular.

Sir,—All friends of Mr. Edalji must be grateful to the Medical Press and Circular for the part it has played in the case. I observe, however, that you now think finality has been reached. I trust that the exhibition of the actual documents in the *Daily Telegraph* and their analysis will convince you that there is as little truth in the accusation that Edalji wrote the letters as that he did the outrages. In this respect a fresh injustice has been done. The man who did the deeds wrote the letters, and that man was neither directly nor indirectly connected with George Edalji.—I am, Sir, yours truly,

Arthur Conan Doyle.

The Grand Hotel, London, May 24th, 1907.

[We are much obliged to Sir Arthur Conan Doyle for giving us this further information, and we shall be very glad to see the actual documents. In the absence of any fresh light, we are of course bound to accept tentatively the interesting opinion of Sir Arthur Wilson and his colleagues.—Ed. M. P. and C.]

LAW FOR LAWYERS AND LAW FOR DOCTORS.

To the Editor of The Medical Press and Circular.

Sir,—The grotesque inequality and absurdity of the law, which, be it remembered, represents the attitude of the State towards the professions of law and medicine respectively, are illustrated daily in one direction or another in the newspaper press. The bare record of these illustrations would occupy fully a page of the medical press weekly. I trust you will continue to keep the matter before the profession by publication at least of samples of the worst anomalies. One of such examples appears in the *Times* of May 22nd, a qualified solicitor was summoned at Bow Street on May 21st charged with "wilfully and falsely pretending to be a solicitor." It turned out that the defendant was a fully qualified man, and had been on the rolls for many years, but his certificate had been refused last year in consequence of his being an undischarged bankrupt. The defendant pointed out that there was nothing dishonourable about his bankruptcy and no allegation against his professional integrity. There had been no false representation on his part, he was acting for an old unfortunate client. He was, nevertheless, fined £5 and costs, or imprisonment in default of distress. Contrast this case with what is going on under medical law, or, rather, in the absence of medical law. An abortion-monger who had been previously convicted and struck off the medical register was recently sentenced to penal servitude, having re-commenced his old trade soon after release from prison. He employed the title of "Dr.," and was not interfered with for this, nor need he have been interfered with if he had refrained from commission of crime bringing him within the reach of ordinary law. Many convicted offenders expelled from the profession are practising under similar false pretences, mostly engaged in nefarious forms of quackery, advertising cures for hopeless cases of cancer and consumption, which ought to bring them within the clutches of the law if the State showed proper concern in the protection of the classes—the helpless victims of disease, who have most claims upon its guardianship. It cannot be believed that the present state of things would be allowed to go on for long if the profession would unite, force attention to their case, and demand the needed reforms. If the profession cannot prove their entire unselfishness, they can at any rate demonstrate conclusively that what they ask for is required a thousand times more for the protection of the people than for their own advantage.

I am, Sir, yours truly,
Henry Sewill.

Hotel Bernascon,
Aix-les-Bains,
May 22nd, 1907.

LONDON HOSPITALS AND GENERAL PRACTITIONERS.

To the Editor of The Medical Press and Circular.

Sir,—Your correspondent, "General Practitioner," seems to have missed the point of "R. L.'s" letter, which I take to be that if hospitals were State-supported, and therefore State-managed, the present members of their staffs would cease to serve in an honorary capacity; but that this would be no great loss as a whole. Perhaps not, but would they so cease? However irksome and troublesome a hospital may be, it is sure that the man with scientific ardour will always seek it because of the opportunity afforded him for the observation of disease. Ordinary private practice is notoriously of little use for purposes of study and self-improvement, because we have not the means of continuous and careful observation. However far from ideal hospitals may be, they form the nearest approach to furnishing "laboratory conditions" that is possible in this fallacious world. For this reason, State hospitals could always rely on securing a highly-qualified staff of honorary physicians. It is possible, too, that if they paid their staff adequately for their work, they would secure the cream of the men who now leave hospital and go into practice, because of the necessity of making a living for themselves as soon as possible. At present, of course, "the highest skill in the medical world" is obtained by paying for it. Hospital posts are not bought and sold with West Ham candour, but they are a question of means, primarily, secondarily, and (almost) entirely.

I am, Sir, yours truly,
Another G. P.

London, S.E., May, 20, 1907.

OBITUARY.

SIR JOSEPH FAYRER, Bart., K.C.S.I., M.D., F.R.S.

We regret to announce the death of Sir Joseph Fayrer, Bart., K.C.S.I., Physician Extraordinary to the King, at Falmouth, in his eighty-third year. Though Sir Joseph had been ailing for some time, his illness became dangerous only ten days before his death. Sir Joseph Fayrer, was born at Plymouth in 1824. Educated privately, he began medical study at the Royal Naval Hospital, Bermuda, and continued it at various medical centres. The year 1847 saw him a member of the Royal College of Surgeons of England, and subsequently he obtained the M.D. of Edinburgh and the Fellowships of the Royal Colleges of Surgeons of England and of Edinburgh and of the Royal College of Physicians of London. At the age of twenty-three he entered the Royal Navy as assistant-surgeon on His Majesty's ship *Victory*, two years later transferring to the Army Medical Service as an assistant-surgeon in the Royal Artillery, and again a year later to the Bengal establishment of the Indian Medical Service. His career in India, thus commenced in 1850; it continued till 1874, when he returned to England and became Surgeon-General, President of the Medical Board of the Indian Office and a consultant of wide repute, not giving up work finally until 1904. His work in India brought him the appointment to the Residency of Lucknow, and thus led to his presence as senior medical officer throughout its siege during the Mutiny in 1857. He was one of the Council of War summoned to decide the question of defence or retreat, and it was in his house, one of the principal points of attack, that the Brigadier-General, Sir Henry Lawrence, eventually succumbed. Subsequently Dr. Fayrer and the medical men associated with him during the siege received the thanks of the Governor-General in Council in a General Order, and he was promoted in rank. In 1867 he received the Companionship of the Star of India, and in the following year was made Government Trustee of the Indian Museum. Three years later he was selected to accompany the Duke of Edinburgh during his tour in Upper India, and in 1871, while still in India, was appointed Honorary Physician to Queen Victoria. After his return to England and his appointment to the India Office he again went out to India, this time in the suite of the King, then Prince of Wales, during his Indian tour in 1875-6. On its termination he was appointed honorary physician to his Royal Highness and made K.C.S.I., being raised to the position of Physician Extraordinary and created a baronet on the accession of King Edward to the throne. Fayrer's scientific attainments met with wide recognition both at home and abroad, and he received many corresponding honours. Thus, in addition to being elected a Fellow of the Royal Society of London, he was LL.D. of the University of Edinburgh and St. Andrews, and at one time President of the Epidemiological Society of Great Britain, of the Medical Society of London, and Consulting Physician to the Charing Cross Hospital. Similarly he was elected to the honorary membership of many foreign societies, such as the Academy of Medicine of France, the Royal Academy of Science of Lisbon, the Royal Academy of Medicine of Rome, and the College of Physicians of Philadelphia. He was also a Knight of Grace of the Order of St. John of Jerusalem.

JOSEPH GROVES, J.P., B.A., M.B.Lond.

We regret to record the death, on May 21st, of Dr. Joseph Groves, of Carisbrooke, Isle of Wight, in his sixty-eighth year. Dr. Groves was for a quarter of a century medical officer of health for the rural district of the Isle of Wight, in which position he worked courageously for the sanitary improvement of the island. He also took a leading part in helping forward movements for higher education; whilst as president of the Isle of Wight Horticultural Improvement Association and of the Isle of Wight Amateur Athletic Club he did much for horticulture and sport. He was formerly president of the southern district of the British Medical Association, and last year he presided over the preventive medicine section of the meetings of the British Medical Association in Canada as the English vice-president of that section. He was a member of the council of the British Medical Association and lately President of the Incorporated Society of Medical Officers of Health, and he was a Fellow of the Geological Society, the Royal Meteorological Society, and the Statistical Society.

DAVID MacMAHON BROWNE, L.R.C.P. and S. Edin.

We regret to record the sudden death of Dr. MacMahon Browne, of Tooting. Deceased had been in good health until the Saturday before his death, when he took to bed with what he described as a heart attack. On the Monday after a severe attack of angina, he paid a visit to a patient's house, where he said that if it had not been for the serious condition of her baby he would not have left the house. Soon afterwards he fell to the floor and died. Deceased was medically educated in Edinburgh, where he took the double qualification in 1882.

REVIEWS OF BOOKS.

A NURSES' VADE MECUM. (a)

This well-intentioned little manual has been compiled from "notes and jottings taken down during a course of twenty-seven years of nursing, and twenty years of instruction and training of nurses, in various countries," but in spite of this, seems fairly up-to-date. At all events the author should know something of what nurses need. So many admirable handbooks on nursing are now available that we should have thought that there would have been but little demand for such a necessarily restricted work as this. Like all books of this class it has the defects of its supposed virtues. As a ready source for suggestions and directions it should be of help to many nurses who in district or other work have often to do the best under difficult conditions and acting more or less on their own initiative; but it is to be hoped that it will not be relied upon to an extent which will displace more thorough and complete manuals.

FLEMING'S PRACTICE OF MEDICINE. (b)

This volume presents the student or practitioner with an excellent, if somewhat condensed, practice of medicine. The author has set out with the intention of writing a short book upon a large subject, and he has achieved that most difficult task in a fairly satisfactory manner. Here and there he is content to state principles and leave the student to work out their application. Speaking of the diet in typhoid fever, he remarks that there is much difference of opinion as to whether we should order milk, with egg flip and other easily digested and nourishing foods, or whether we should be content with a minimum of other nourishment." "*The principle governing the dietetic régime is to have as little waste matter reaching the inflamed portion of the intestine as possible, and probably a middle course is desirable.*" In a matter of such importance we should have preferred to have a clear statement of the writer's own experience and practice. In acute rheumatism we are told the "proper medicinal treatment is much disputed." That observation hardly seems to recognise the firm belief of most practitioners in some form or other of the salicyl compounds. The section of the book dealing with diseases of the nervous system is specially clear and helpful. In the space at our disposal it is impossible to enter into any detailed criticism. Broadly, however, it may be stated that Dr. Fleming has produced in this book a general outline of individual disease, the details of which must be filled in by the student himself. The author's experience as a lecturer on medicine to the Royal Colleges and as an assistant physician to the Royal Infirmary, Edinburgh, ensures the amount and the accuracy of his information. This unassuming book, indeed, is worthy of the best traditions of the Scotch school, and may be safely recommended to all who need an authoritative if rude map to the great field of modern medicine.

LABORATORY NOTES.

The demand for drugs in tablet form has led the Bayer Company, Ltd., to put up several of their well-known products in that shape, and we have samples of Aspirin, Helmitol, Tannigen, Trional-Bayer and Veronal, all in 5-grain doses, and Heroin Hydrochloride in 1-24th grain doses. These preparations will doubtless be welcomed by many who are in the habit of prescribing these useful drugs.

Messrs. Parke, Davis and Co. are introducing in Iodalbin, an ioda-proteid compound containing 21.5 per cent. of iodine, for which it is claimed that while producing the same therapeutical effects as the alkaline iodides, it does not give rise to gastric irritation and iodism. They also present some new compound tablets—Phenol Phthalein, intended for use as an habitual laxative. The aperient qualities of the main drugs are reinforced and modified by addition of Belladonna and Strychnine.

The same firm have also brought forward a nutritive Liquid Peptone, in which prime beef is reduced to peptone by means of Bromeline—the proteid-digesting ferment of pine-apple juice—and extract of malt. The same preparation is also made up with beech-wood creosote and guiacol under the name of Nutritive Liquid Peptone with Creosote. Their use is recommended especially in wasting diseases in which the digestion is impaired.

Several new and interesting preparations have lately been brought out by Messrs, Burroughs and Wellcome, among which we may note an Elixoid of Formates, Quinine Acetyl Salicylate, Iron Arsenate (soluble), and Bismuth Citrate (soluble), "Wellcome" brand. The Elixoid Formates Compound contains in each fluid ounce, Calcium Formate 12 grains, Sodium Formate 6 grains, and Magnesium Formate 6 grains. Two fluid drachms in water, thrice daily after food, is said to form a pleasant and useful nerve and general tonic.

Quinine Acetyl Salicylate is a drug which is said to combine the advantages of Quinine and the Salicylates without any free salicylic acid being given off to irritate the stomach, the acetyl-salicylic acid that is formed not being a gastric irritant. In all rheumatic and periodic conditions, especially in such as exhibit both features, the drug would commend itself for trial.

Iron-Arsenate (soluble), "Wellcome" brand, is intended to supersede the unsatisfactory Ferri-Arsenas of the British Pharmacopœia. This drug is insoluble in water and variable in composition as officially prepared, and Messrs. Burroughs and Wellcome are now able to supply in their substitue a preparation which is readily soluble in water, miscible with other drugs, and of staple composition. The Bismuth Citrate (soluble) "Wellcome" brand, is designed to replace the Bismuth Ammonium Citrate preparation of the United States Pharmacopœia, and should also be useful in Great Britain.

Cases of spotted fever have occurred sporadically at Constantinople during the last two months, and with increasing frequency in the past fortnight, when there have been one or two deaths daily, chiefly among infants and young people.

(b) "A Short Practice of Medicine." By Robert A. Fleming, M.A. F.R.S.E., Lecturer on Medicine, Royal Colleges, Edinburgh, &c., &c. London: J. and A. Churchill. 1906.

Weekly Summary of Medical Literature, English and Foreign.

Specially compiled for The Medical Press and Circular.

RECENT SURGICAL LITERATURE.

Acute Dilatation of Stomach.—Connor (*Amer. Jour. of Med. Science*, Philadelphia, March, 1907) bases his study on 82 recorded cases of acute dilatation of the stomach, two personal cases and 18 cases of mesenteric obstruction of the duodenum. He considers acute dilatation of the stomach a disease of considerable clinical importance, one which develops under a variety of conditions, but is especially frequent after operation done under general anæsthesia. In the majority of cases reported, there was found an associated dilatation of the duodenum; in fact, in a large proportion of cases—about one-half—the dilatation is associated with, and seems to result from, some form of obstruction of the duodenum. The most common cause of such obstruction is found to be constriction of the lower end of the duodenum, between the root of the mesentery and the vertebral column. The constriction occurs when the mesenteric root, with the superior mesenteric artery, which runs in it, is stretched tightly across the duodenum as the result of traction exerted by the small intestine hanging over the brim of the pelvis. Although great dilatation of the stomach would doubtless increase the liability to mesenteric obstruction by crowding the intestines into the pelvis, Connor is of the opinion that in some cases at least the duodenal obstruction is primary. The mortality among the reported cases was 72 per cent., but Conner says that there is much evidence to show that the disease can usually be controlled and cured, if the diagnosis is made and suitable treatment begun before complete collapse of the patient has occurred. D.

Retention of Urine in a New-born Female Child.—Rudaux (*Paris Med. Journ.*, April) describes the case of a normal female child born at term. After twenty-four hours she had not passed any urine, but suffered from spasmodic attacks, evidently of dysuria. There were œdema above the pubis and hypogastric distention, the vulva bulged outwards, the hymen forming a convex septum. On pressing the hymen almost solid mucous escaped. A stout loop of silkworm gut was bent and passed into the minute orifice of the hymen. This broke up the solid mucous, and a considerable quantity was emptied out of the dilated vagina. Another loop of gut was introduced into the urinary meatus, and at once a strong jet of urine escaped. There was no further trouble, the infant micturating normally within a few hours, and next morning the œdema and distention had disappeared. G.

Primary Suture of the Median Nerve.—Stirling (*Intercolonial Med. Journ.*, March, 1907) reports the case of a wood-carter whose arm had been caught in machinery. There was a large, foul gaping wound, just above the inner side of the right elbow, dividing the structure down to the joint, and among them the brachial artery and the median nerve. It was found that three inches of the nerve had been destroyed. The ends were united as well as possible with catgut and the wound partly closed; there was a considerable amount of sepsis; the wound re-opened and granulated up. A month later, the wound now having completely healed, the nerve was again exposed and found to be, as was expected, widely separated again, the severed ends being fully three inches apart. The sciatic nerve of a small dog was grafted on to the freshened ends of the median. This operation was aseptic. Twelve months later the patient reports, "My arm is very much improved. I am now able to bend and grip anything with the last three fingers of the hand. The first finger and thumb I can also bend very well, but cannot grip so well with these. The arm itself is much stronger, and I can move it very freely. The only drawback is the skin of the hand, which is very soft and tender. The least little knock breaks it, and it heals very slowly then." Evidently the motor-functions of the nerve have been almost completely established, while the sensory, as is so often the case in lesions of the musculo-spiral, have been only partially restored. G.

The Treatment of Hæmorrhoids by Injections of Carbolised Glycerine.—Vulliet describes a method (*Rev. Med. de la Suisse Romand*, December, 1907) which has been practised for several years by Prof. Roux with marked success. The advantages claimed for the method are freedom from hæmorrhage, the short duration the patient is confined to bed, and the simplicity of the instruments required for the operation, a stout hypodermic syringe and a 60 per cent. solution of carbolic acid in glycerine being all that is necessary. With the patient under an anæsthetic, the piles are made to protrude in the ordinary way; the needle is introduced into the base of each pile in turn, and one or two drops of the solution injected, care being taken that none of the solution gets on to the surface of the piles. It is better to keep the bowel continuously douched to prevent this occurring. Immediately after the operation the piles become swollen. They are left protruding from the bowel, well smeared with vaseline. For a few hours this swelling continues, the piles becoming dark purple and even showing small areas of sloughing tissues, but in three days shrinking begins, which may be aided by hot applications. There is little pain, and the patient need only be confined to bed for five days. It is quite unnecessary to constipate the patient. For some weeks fibrous nodules remain about the anus, but these gradually disappear and cause no trouble. While the immediate results are rapid, relapses have seldom been known to occur. G.

Pus Tubes in the Male.—Belfield (*Medical Record*, May 4th, 1907) considers that pus infection of the seminal tube, including the vesicle, in the male, appears to be quite as frequent as pus infection of the Fallopian tube in the female. It is not so often recognised, for its usual symptoms—pyuria, frequent and painful urination, and partial or complete retention of urine—are usually referred to the bladder and prostate, and the patient therefore treated for cystitis and prostatitis. In gonococcal infection when complete retention of urine is terminated by a sudden discharge of pus into the urethra, it is usually diagnosed as prostatis abscess, and often when caused by abscess formation in the seminal vesicles. The non-gonorrhœal infections of the seminal vesicle in men over 40 years of age the author considers are often labelled prostatic hypertrophy, as they cause the same symptoms. These are the cases of alleged prostatic enlargement, which were benefited by vasectomy, when that operation was popular. The author's treatment of the condition consists essentially in opening the vas, stitching the cut edges of the skin, and injecting through a curved hypodermic needle any chosen solution into the proximal vas. This liquid traverses the vas and ampulla, and enters the seminal vesicle. By digital massage from the rectum, the injected liquid can be expressed into the urethra if desired. Through the fistula daily injections of the vesicle can be made as long as seems necessary, after which the fistula is easily closed. Complete transverse section of the vas may safely be made, if preferred, since anastromosis of the cut ends, and restoration of the lumen can be easily accomplished. The first injection should not exceed thirty to sixty minims, lest spermatic colic and retention of urine be provoked. S.

Medical News in Brief.

Royal College of Surgeons in Ireland.

The following candidates having passed the necessary examination, have been admitted Fellows of the College:—F. J. Cahill, L.R.C.S.I., etc.; R. H. Dickson, L.R.C.S.I., etc.; T. W. A. Fullerton, B.Ch., etc., R.U.I., Major, I.M.S.; P. E. Hayden, L.R.C.S.I., etc.; H. Stokes, B.Ch., etc., Univ. Dub.; P. D. Sullivan, L.R.C.S.I., etc. The following candidates have passed the primary part of the Fellowship examination:—W. F. O'Connor, B.Ch., etc., R.U.I.; Miss E. R. Benjamin, R. Charles, F. J. Colgan, E. A. Gregg, P. M. J. Power, R. S. White.

Association of Physicians of Great Britain and Ireland.

The first general meeting of this Association was held on Thursday and Friday last, May 23rd and 24th, in the rooms of the Royal Medical and Chirurgical Society, Hanover Square, London. The chair was occupied by Sir R. Douglas Powell, Bart., President of the Royal College of Physicians, and there was a very large attendance of members. The opening portion of the meeting was devoted to business matters, and thereafter a large amount of good scientific work was submitted. The time of meeting was from 10 a.m. to 6.30 p.m. daily, with intervals for luncheon and tea. On Thursday evening the members dined together at the Trocadero Restaurant. The Association is to meet next year in Edinburgh.

Trinity College, Dublin.—Post Graduate Classes.

A reference to our advertising columns will show that the post-graduate classes, which have been so successfully carried on during the past three years, will commence on 17th June. Trinity College was the first medical school in Ireland to organise special classes for qualified men, and each year the numbers entering for the course have increased. This year the classes will be conducted on the same lines as in former years. The syllabus before us shows that instruction will be given in medicine, surgery, diseases of the eye, throat, nose, ear and skin in the forenoons, while the afternoons will be occupied with clinical pathology, operations, anatomy, X-ray work, physiology, and the like. An attractive and popular feature of the course is the possibility of obtaining rooms in College and dining at Commons. As the number of rooms is limited, early application by those intending to reside in college is desirable. Financial details are given in the advertisement, and any information not contained therein may be had from the Honorary Secretary.

Society of Apothecaries of London, May, 1907.

The following candidates, having passed the required examinations, have received the L.S.A. Diploma of the Society, entitling them to practise medicine, surgery and midwifery:—H. S. Burnell-Jones, S. A. Mahmood, E. Moir, C. C. Morrell, R. Spears, and E. W. Squire.

St. Bartholomew's Hospital.

The annual report of this Royal hospital shows that the past twelvemonth was a successful one. The gross rentals increased by £1,118, and the expenditure decreased by £1,846, the result being an advance of £2,964 in the sum carried to the general account for hospital purposes. The total income is stated at £72,919, and the expenditure at £75,557, a deficit of £2,638 appearing therefore at the close of the year. The principal items of outgo were salaries and wages, £25,701; provisions, £13,183; domestic, £12,171; establishment charges, £6,656; surgery and dispensary, £7,513; administration, £2,199; extraordinary expenditure, £4,030; convalescent and home, £3,252. The legacies received during the year were £2,295, and of this £1,427 has been applied to the rebuilding fund. With regard to that fund the treasurer states that the receipts for the twelvemonth only amounted to £13,838, raising to £118,371 the total sum given or promised, exclusive of £3,208 for the pathological block, £2,459 for the nurses' home, and £959 on account of Dr. Norman Moore's book on the hospital. As to the work done it is stated that the number of in-patients treated was 7,615, the daily average being 556, and the average period of residence 26.6 days. The casualty patients numbered 75,683 medical and 49,223 surgical. The total number of new cases was 126,021, and of attendances 287,231. Inquiry was made into the pecuniary condition of 8,673 patients, and as a result 103 could not be found at the address given, and 277 were considered to be unsuitable for gratuitous aid. The number of patients sent to the Convalescent Home was 1,070, and in addition 201 patients were received at other homes.

Proposed National Health Authority.

A meeting of representatives of the county councils of Northumberland and Durham and the urban sanitary authorities of Newcastle-upon-Tyne, and other Tyneside towns was held yesterday in Newcastle to consider measures to be taken to combat tuberculosis. The following resolution was carried: "That, in the opinion of this meeting, it is desirable that a permanent union of the sanitary authorities of England and Wales be established as a supreme national health authority with the object of safeguarding and promoting the public health interests of the people at large against tuberculosis and other dangers to the public health."

Society for Relief of Widows of Medical Men.

At the Annual General Meeting of the above Society, Dr. Blandford, president, in the Chair, a resumé of the work done by the Society during the past year was presented by the secretary. Ten new members were elected, nine died and one resigned. The Society consists at the present time of one honorary, 140 life, and 145 paying members, making a total of 286, which, considering the number of medical men who are eligible for membership, is but a very small proportion. The invested funds of the Society amount to £98,960, from which is derived in interest the sum of £3,114 4s. 11d.; £334 19s. was received in subscriptions and donations. The working expenses for 1906 were £217 10s. 5d. Amongst the annuitants of the charity, namely 54 widows and 21 orphans, the sum of £3,268 10s. was distributed, each widow receiving on an average £50 and £10 extra at Christmas, and each orphan £10 and £3 extra at Christmas.

The Copeland Fund is a special fund which enables the Society to grant to any widow or orphan already in receipt of the Society's ordinary relief, extraordinary relief in special circumstances of unusual distress, such as blindness, paralysis, insanity, severe disabling accident, or grave permanent disease, and to continue such extra relief in the case of orphans as the Court of Directors may think fit.

During the year six widows, in receipt of grants, died. One, whose husband had paid a life subscription fee of £21, received £900; another, whose husband had paid the maximum amount in annual subscriptions, namely, £52 10s., received £697, the remaining four widows had received on an average £600 each. Five widows were elected during the year, and on December 31st there were 47 widows and 20 orphans in receipt of grants. One of the widows has been on the books since 1854, and has already received over £2,000.

Relief is only granted to the widows and orphans of deceased members, who have paid their annual subscription for three years, or are life members.

The Directors strongly urge upon members of the medical profession, especially the younger ones, the desirability of joining the Society. Membership is open to any registered practitioner, who at the time of his election is resident within a 20-mile radius from Charing Cross. The annual subscription is two guineas; every member who shall have paid this sum for twenty-five years becomes a member for life. Further particulars may be obtained from the Secretary, 11 Chandos Street, Cavendish Square, W.

NOTICES TO CORRESPONDENTS, &c.

☞ **CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office: if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions, the same rule applies as to office; these should be addressed to the Publisher.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessary for publication but as evidence of identity.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies. Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

MEDICUS.—The newspaper report which has reached us through the ordinary channels, is at variance with our correspondent's statement. We will, however, make inquiries into the matter, with a view to dealing with it.

CONTRACT.—The appointment you mention is one that should not be applied for without careful inquiry of the local members of the profession. There has been considerable dispute about the conditions attaching to it, and if you apply and are elected you may find yourself isolated from your fellow-practitioners in the town.

CASES WHICH PUZZLE THE DOCTORS.

THERE have been many parallels to the case of the young man in the Croydon warehouse, whose voice, lost through an accident seven years ago, has been restored through the shock produced by an exploding syphon of soda-water. Not long ago, John Moore, an ex-soldier, of Gosport, who had been dumb for four years, suddenly recovered his speech in an alarm caused by a trivial bicycle accident. More remarkable still was the case of Mathias Steingruber, who was thrown from his horse in a charge in the Mexican war, sixty years or so ago. For more than half a century his mind was an absolute blank—the machinery of the brain stood still, until mind and memory were restored by a severe blow on the head from a piece of wood thrown from a circular saw. A few years since a Bavarian cattle dealer, who had long been dumb, was restored to speech by a horse's kick; William Wilkinson was "stone-deaf" until an accident in a Leeds street gave him back his hearing; and a gentleman who had been blind for seventeen years recovered the use of his eyes after an operation which followed injury in a carriage accident near Exeter.—*Westminster Gazette.*

DUNS SCOTUS.—Several sanitary authorities have used their isolation hospitals as sanatoria for consumptives during slack times, and it might be a solution of your difficulty if you could get permission to use your small-pox hospital for the purpose. The Galashiels Sanatorium, which has just been opened, was originally built for a small-pox hospital.

DR. R. A.—If you want to place your patients with a colleague, you should apply to the Hon. Secretary, Association of Medical Men Receiving Resident Patients, 56 Outer Temple, Strand, W.C., A list of medical men willing to receive patients, together with information as to accommodation, fees, etc., is kept by the Secretary for the use of inquirers.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, MAY 29th.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Mr. J. Cantile: Clinique.—(Surgical.) 5.15 p.m.: Lecture:—Dr. P. Stewart: The Diagnosis of Disseminated Sclerosis.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—Cliniques:—2.30 p.m.: Skin (Dr. Meachen), Eye (Mr. Brooks), Medical Out-patient (Dr. Whipham).

THURSDAY, MAY 30th.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY (20 Hanover Square, W.).—5.30 p.m: General Meeting. Election of Officers for the ensuing year. 6 p.m.: Address:—Dr. N. Moore: Air, Water, and Situation. 7.30 p.m.: Annual Dinner at the Trocadero Restaurant, Piccadilly Circus, followed by an Entertainment.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Mr. Hutchinson: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Dr. F. M. Sandwich: Cerebro-spinal Fever.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Gynæcological Operations (Dr. Giles). Cliniques:—Medical Out-patient (D. Whiting), Surgical Out-patient (Mr. Carson). 3 p.m.: Medical In-patient (Dr. Chappel). 4.30 p.m.: Special Demonstration on Medical Cases (Dr. Whiting).

FRIDAY, MAY 31st.

EPIDEMIOLOGICAL SOCIETY (11, Chandos Street, Cavendish Square, W.).—8.30 p.m.: Papers:—Prof. A. Holst (Christiana University): Studies concerning Ship Beri-beri.—Prof. Holst and Dr. T. Frolich (Christiana University): Polyneuritis in Poultry (Polyneuritis Gallinarium Eijkman) and Scurvy in Guineas-pigs.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Dr. J. Horne: Clinique. (Throat.)

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—9.30 a.m.: Clinique: Surgical Out-patient (Mr. H. Evans). 2.30 p.m.: Surgical Operations (Mr. Edmunds). Cliniques:—Medical Out-patient (Dr. Auld), Eye (Mr. Brooks). 3 p.m.: Medical In-patient (Dr. Leslie).

Vacancies.

Corporation of the City and County of Newcastle-upon-Tyne.—Assistant Medical Officer of Health. Salary £300 per annum, with board, lodging, etc. Applications to the Medical Officer of Health, Town Hall, Newcastle-upon-Tyne.

Egypt.—Sub-Inspector of Ophthalmic Hospitals. Salary £500 a year, with two months' salary in lieu of travelling expenses to and from England. Applications to the Director-General, Department Public Health, Cairo.

The Hospital for Sick Children, Great Ormond Street, London, W.C. Anæsthetist. An honorarium of 15 guineas. Applications to the Secretary. (See advt.)

Middlesbrough: North Ormesby Hospital.—House Surgeon. Salary £120 per annum, with apartments and board. Applications to R. T. Milner, Secretary, Royal Exchange.

The Hospital for Sick Children, Great Ormond Street, London, W.C.—A House Surgeon. Salary £20 for six months, washing allowance £2 10s., with board and residence in the Hospital. Applications to the Secretary. (See advt.)

City of London Hospital for Diseases of the Chest, Victoria Park, E.—Resident Medical Officer. Salary £120 per annum, with board, etc. Applications to the Secretary.

Alnwick Infirmary.—House Surgeon. Salary £140 per annum, with furnished apartments, attendance, coals, and gas. Applications to Wm. T. Hindmarsh, Honorary Secretary, 26 Bondgate Without, Alnwick.

London Temperance Hospital, Hampstead Road, N.W.—Resident Medical Officer. Salary £120 per annum, with board, lodging, and washing. Applications to A. W. Bodger, Secretary.

Appointments.

CHARLES, HERBERT, M.R.C.S., L.R.C.P.Lond., Assistant Anæsthetist to the Middlesex Hospital.

CLEARY, M., L.R.C.P. and S.Edin., L.F.P.S.Glasg., Certifying Surgeon under the Factory and Workshop Act for the Newport District of the county of Mayo.

DOLAMORE, W. H., M.R.C.S., L.R.C.P., L.D.S.Eng., Lecturer on Operative Dental Surgery at the Royal Dental Hospital of London, Leicester Square, W.C.

FINDLAY, W. D., M.B., C.M.Glasg., Certifying Surgeon under the Factory and Workshop Act for the Middleton District of the county of Lancaster.

GELLATLY, ANDREW, M.B., C.M.Edin., Medical Officer of Health of Droys'den, Manchester.

HIBBERT, J. COOTE, M.D.Lond., D.P.H., Medical Officer of Health of the Borough of Warrington.

LOGAN, W.A., F.R.S.C.Eng., L.R.C.P.Lond., Clinical Assistant to the Chelsea Hospital for Women.

Births.

CRAIG.—May 22nd, at 18 Merrion Square, Dublin, the wife of James Craig, M.D., of a daughter

MOONEY.—On May 21st, at 22 Lower Baggot Street, Dublin, the wife of Herbert Mooney, M.B., of a daughter.

MCNEIGHT.—On May 22nd, at Thaxted, Essex, the wife of W. R. P. McNeight, M.D., T.C.D., of a daughter.

REEVES.—On May 12th, at 6 Streatham Hill, London, S.W., the wife of Albert Reeves, M.R.C.S., L.R.C.P., of a daughter (still-born).

Marriages.

MARSHALL—DE BRUNO-AUSTIN.—On May 22nd, at St. James's, Piccadilly, London, Richard Wildridge, younger son of Dr. John Marshall, late of Coatbridge, N.B., to Gwendoline Lucy, elder daughter of F. J. de Bruno-Austin, of Hampton Wick.

RIVIERE—OSLER.—On May 22nd, at Rosslyn Hill Chapel, Hampstead, Clive Riviere, M.D., son of Briton Riviere, R.A., to Henrietta Maria, daughter of Thomas Osler, of Hampstead.

STANWELL—GILLING.—On May 23rd, at St. John's Parish Church, Chipping Barnet, F. Skey Stanwell, M.D., of Palmers Green, Middlesex, son of the late Dr. Stanwell, of Cambridge, to Edith Elizabeth, second daughter of Henry R. Gilling, J.P., of Barnet, Herts.

Deaths.

COGHILL.—On May 24th, at 16 Clareville Grove, London, S.W., Agnes, the wife of the late J. G. Sinclair Coghill, M.D., F.R.C.P (E.), of Ventnor, I.W., formerly of Edinburgh.

GROVES.—On May 21st, at Carisbrooke, Isle of Wight, Joseph Groves, B. A., M.B.Lond., in his 68th year.

MISKIN.—On May 22nd, at 160 York Road, Lambeth, Nicholas Miskin, M.R.C.S., L.S.A., in his 97th year

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXIV. WEDNESDAY, JUNE 5, 1907. No. 23

NOTES AND COMMENTS.

English and German Sanatoria.

WHATEVER mistakes of overstatement have, in the past, been made by anti-tuberculosis enthusiasts, it will be agreed on all hands that the sanatorium is the most suitable place for the tuberculous worker who cannot afford efficient treatment at home or abroad. The prospect of arrest which was so freely promised is, of course, far from assured in many cases, but on the other hand in a goodly proportion it takes place. In many such arrest is only temporary, but in some it is undoubtedly permanent. At all events, there is no sort of alternative to sanatorium treatment which holds out any reasonable prospect of relief, and certainly none whereby the patient can be properly separated from the healthy. The bulk of working-class consumptives live and sleep in the same room with several members of their families, and from the preventive point of view the sanatorium offers important attractions. But though in the last few years sanatoria have been springing up in all parts of the country, the number of beds available for workers who can afford to pay nothing for their treatment is pitiably small; it is said that there are less than a thousand, a number which contrasts ludicrously with the demand that an annual mortality of 70,000 persons from tuberculosis connotes. At the Congress of the League against Tuberculosis, held at the end of last month in Germany, it was stated that there are at present 87 sanatoria in Germany for the use of the masses, and that these provide no less than 8,422 beds. Besides these, there are 17 further sanatoria for children suffering from tuberculosis, and 35 private hospitals. The figures as they stand, throw our own into ignominious contrast, and it is proposed by the League still further to increase the accommodation for children and young people, so that this country has an enormous amount of lee-way to make up before it can hope to rival Germany in its care for the consumptive poor.

The Sphinx Club and Professional Advertising.

THE Sphinx Club, we learn from a press report, devoted its April banquet to a discussion on "Professional Men and Advertising," several representatives of the medical and legal professions being invited to give their views on the subject. The proceedings being somewhat of a convivial nature it was natural perhaps that the discussion should have been devoted rather to playful pleasantries than to the serious aspects of the question, but it was noticeable that most of the medical speakers, who for some reason were more fully reported than the lawyers, seems to have been imbued with ideas as vague as they are peculiar. One orator rested the extraordinary doctrine that no general practitioner could afford to advertise—even if permitted to do so—on the still more extraordinary statement that it cost £1,400 to take one page in the advertisement columns of a medical journal. The gentleman in question may rest assured that for a hundredth of that sum any medical journal would be glad to grant him a whole page on which to display his encomiums on himself. Another speaker gave vent to the equally absurd declaration that so long as the characteristics described in advertisements were limited to goods or animals, the public would give them a hearing, but when they were applied to persons they were regarded as ridiculous and vain-glorious puffs. If this were so, it would be difficult to account for the success of persons like the physical culturists, or the "beauty specialists," or the hernia or deafness curers, or the thousand other professors of their own powers in the treatment of disease. Perhaps the most sensible statement made by any of the guests was one to the effect that if the advertisements one sees were true, there would be no need for the medical profession at all.

Theodore Williams Scholarship.

THE opportunities for saving money presented by the pursuit of medicine are so poor that it is not a matter for wonder that few medical men indeed find themselves in the position to advance the science or study of medicine by the giving of scholarships. It is then all the more pleasing to be able to record the really handsome benefaction just founded at Pembroke College, Oxford, by Dr. Theodore Williams. This is to take the form of a scholarship of £100 a year, to be known as the "Theodore Williams Scholarship," and is to be held by an honours student of the natural sciences who has the *bona fide* intention of proceeding to the degrees of B.M. and B.Ch., and of eventually practising medicine. The scholarship under proper safeguards is tenable for four years at Oxford, and may be extended for one year more at the discretion of the Master and Fellows. Of course, £100 a year will not keep a student at Oxford, but it will go a long way towards it, and as English universities do not enjoy Carnegie endowments, the poor English student has hitherto had very little chance of getting through a course at the older foundations. We congratulate Dr. Theodore Williams on this wise and generous foundation, which should be all the more appreciated in that the founder has made the necessary pecuniary sacrifices during his life-time.

Expert Fees in India.

One of the disadvantages that medical men suffer under is that in any system they nearly always find themselves in a position of subordination to men of other callings, and often of no callings at all. This is particularly galling in a bureaucratic country like India, where all the services are jealous of the "doctor," and try in various ways to snub and offend him. A glaring instance of this policy occurred in the High Court of Calcutta, where an action involving an estate of several lakhs of rupees was recently tried, and on the express order of the Registrar, certain highly-placed medical officers in the service were called to give expert evidence as to the sanity of the petitioner. The highest fees named were Rs.500 (about 30 guineas) a day, some of the witnesses taking rather less; and these charges must be considered moderate indeed compared with the size of the estate and the responsibility involved in the decision. Yet when the costs came to be taxed, these fees were cut down to the beggarly sum of Rs.80, and, in the case of one Lieutenant-Colonel, only Rs. 16 were allowed. The judge when appealed to to interfere, refused, owing to a technicality, and the medical officers had to pocket the affront.

Outrageous Scandals in American Asylums.

The State Board of Charities in Illinois has just presented a report on the conditions of the county lunatic asylums under the jurisdiction of that State, which is calculated not only to recall the horrors of the Inquisition, but to make them pale into insignificance. Indeed, the Spanish experts must be regarded as blundering amateurs in the science of torture compared with the artists in charge of the insane of Illinois; that is, if the report is to be believed, and it is hardly possible to doubt an official document of deliberation and responsibility such as the report appears to be. In many counties a system of farming out the insane to the lowest bidder prevails, with consequences that beggar description. Boxes and cages are used for refractory patients, and in them the wretched lunatics are padlocked at night, small holes being cut for ventilation. Steel handcuffs and chains are part of the normal equipment of these ghastly institutions, and vermin and filth of every kind abound. Some of the patients are never washed, and those who are allowed water are given a single bath for use among a crowd of both sexes. Indeed, separation of males from females is considered a refinement of decency to which no countenance should be accorded, and women are consequently violated and outraged without compunction. So horrible and revolting are these disclosures that we can hardly bring ourselves to believe them, but if a tithe be true, we can only say that they constitute such a disgrace to humanity as to call for the combined intervention of every civilised country.

LEADING ARTICLES.

THE BILL TO INCORPORATE KING EDWARD'S FUND.

The Bill to incorporate the King Edward's Hospital Fund has been sent from the Lords to the Commons. In the latter House it passed its second reading, and has now reached its Committee stage. The possibility of amending it in various ways and to almost any degree still remains in the power of the Commons. From rumours that have lately been heard in various quarters, the proposed Bill is not likely to pass into law with the smoothness and celerity that marked its earlier stages. The attention of many members, it seems, has been directed to the principles involved in its proposals, and there is every likelihood that not a few pointed criticisms will be heard when the matter comes on for discussion. We believe that we may claim for the Medical Press and Circular priority in drawing public attention to the defects of the constitution of this important metropolitan fund, and of the undesirability of perpetuating them in the charter of the King Edward's Fund. We may perhaps, therefore, be excused in making some comments on the position. Without doubt the matter is one of some delicacy. No king has ever secured the whole-hearted confidence of our countrymen with anything remotely resembling the enthusiasm that is everywhere accorded to King Edward VII. That loyal feeling has to a large extent sprung from the recognition of the kindness of heart, genuine common-sense wisdom, and unfailing tact that mark the attitude of our great sovereign with regard to his subjects. However, as regards the proposed charter of the Fund which bears his name we cannot help feeling that His Majesty's advisers have not shown their usual soundness of judgment and grasp of modern opinions. The first great fact with regard to the Fund is that it is governed by a small autocratic and non-elective and non-representative board. From this it follows that there is no appeal from its decisions, whether just or unjust. Let us see how this method might work out in practise. The Fund, let us imagine, throws a slur upon a particular hospital by refusing a grant. The hospital can get absolutely no explanation as to why the grant has been refused, so that there is no way of getting at the root of the offence. It is a method comparable in a distant way to the irresponsible decrees of the Star Chamber of evil memory. There is no elective control of members of the Executive of the Fund, and whether it be the case or not it is always open to those who imagine they have a grievance against the Fund to say that a private grudge has been satisfied at their expense. It seems in any case possible that under certain circumstances an undue proportion of power in allotting the vast revenue of the Fund might fall under the control of one or two of its more active members. Sir Edmund Hay Currie to-day holds a dominant voice in the politics of the Fund, but the power that he wields with such absolute fairness and broad-minded wisdom to-day might to-morrow devolve upon a narrow-minded, imperious, and ill-balanced successor. There is, again, the danger that members who hold extreme views in the field of hospital politics may be able to influence the action of the Fund unduly. Take, for instance, the opportunity afforded to a member who maintains that hospital patients should contribute to the cost of their relief, or that a policy of amalgamation should be pressed at all costs upon certain institutions, or that the smaller hospitals should be exterminated. As the proceedings of the Fund are private, and their members are irresponsible, it is open to imagine that any of these extreme individuals may be running his peculiar hobby at the expense of this, that, or the other hospital which is refused a grant. Nay, in some instances certain persons have not been slow to assert that the exclusion of a particular hospital from participation in the King Edward's Fund grant has been due to individual animosity on the part of a member of the Executive. It is, of course, impossible to accept such a suggestion for a single moment; but here again the very irresponsibility of the Fund renders it equally impossible to refute rumours of the kind, however obviously idle, malicious or ill supported. The key to the dissatisfaction, as we have often urged, lies in the non-representative nature of the Fund. We maintain that the Executive should be partly if not wholly elected by the governors, by the hospital staffs, both lay and medical, by the medical profession generally, and by the public who participate in the benefits distributed by the Fund. In this way a wide and instructed guidance would be secured in the administration of the Fund. There is another aspect of the question which we placed before our readers in our issue of May 8th (page 497) in the following words:—"The powers sought are at variance with every principle valued by a free and democratic country, and the most unhappy part of all is that this authority is to be vested in the Prince of Wales, who will thereby incur the odium which the action of the Fund may excite at any time. The proposed constitution is the worst that could have been sought, and the Prince of Wales is the last person who should have been chosen to be the responsible person under such a constitution." These criticisms may perhaps seem somewhat more emphatic than are warranted by the circumstances of the case, but we can only say that they have been written in a spirit of the highest loyalty. In our opinion the Royal Family should be kept strictly out of all controversial matters, especially in a situation of the kind under discussion, where the possibility may arise at any time of the Fund being made the stalking-horse of individual interests. It is to be hoped that both the Metropolitan Hospital Sunday and the King Edward's Funds will revise their constitution upon lines of popular representation such as those adopted by the Hospital Saturday Fund.

THE GENERAL MEDICAL COUNCIL.

The eighty-fifth session of the General Medical Council was opened on the 28th instant by the usual address from the chair. On the present occasion the President, Dr. Donald MacAlister, had nothing of more than ordinary interest to communicate. As regards his own position on the Council, he was able to state that the University of Cambridge had requested him to complete the term of five years to which he had been elected as its representative. In this way Dr. MacAlister is enabled to retain his seat in the Council, in spite of the fact that he has been unexpectedly called by His Majesty to become the resident head of the University of Glasgow. The General Medical Council may be congratulated on retaining the services of so fair-minded and accomplished a president. The present session has been marked by the introduction of the four recently elected direct representatives, Dr. Langley Brown, Dr. L. S. McManus, and Dr. H. A. Latimer for England, and Dr. Norman Walker for Scotland. The last-mentioned succeeds Dr. Bruce, of Dingwall, who for twenty years has rendered valuable service to the Council. In his address the President referred to certain proposed changes in the course of study and examination for medical degrees in the University of Edinburgh, as to which the opinion of the Council had been asked for by the Lord President. The completion was announced of the negotiations for medical reciprocity with the Province of Nova Scotia, to which His Majesty in Council was pleased last year to apply Part II. of the Medical Act, 1896. The Executive Committee had felt justified in granting recognition to Nova Scotian degrees and diplomas on terms which, while they fulfilled the conditions of the Medical Act as regards efficiency, were at the same time satisfactory to the Provincial Medical Boards. An incidental consequence of this recognition was that Canadian medical graduates, who had fulfilled the conditions applicable to the Marine Province, are now eligible for commissions in the Royal Army Medical Corps. Graduates of provincial universities in Canada, other than Nova Scotia, however, are still ineligible for appointments in the medical services of the Crown, and it rests with the universities concerned to remove the disability. Dr. MacAlister reported progress in the Bill proposing amendment in the law relating to the practise of medicine and of dental surgery by joint stock companies. Approved by the Council, that measure had passed the second reading in the Lords without opposition, and had been referred to a Select Committee. The Bill to empower the Society of Apothecaries to confer upon those who had passed its qualifying examinations the title of "Licentiate in Medicine and Surgery" had passed through several of its stages in Parliament. Turning to penal administration, the President reported that the Secretary for Scotland had been pleased to give directions similar to those already given in England and Ireland, which would result in the notification to the Council of all cases in which registered practitioners were convicted in Scotland of offences punishable by fines. This step will undoubtedly strengthen the hands of the Council in the performance of its disciplinary functions in Scotland. It is significant that of late years there has been a considerable decrease of charges of "infamous conduct" brought before the Council. The majority of penal cases now claiming their attention refer to conviction before the ordinary tribunals for crimes or other offences of various kinds. It is satisfactory to note that notwithstanding the expenditure of £870 over the election of direct representatives, the financial year shows a balance of £40 to the good, instead of a deficit.

CURRENT TOPICS.

Science and the English Public.

A few days ago a debate was held in which Professor Halliburton had the courage to oppose the views of Miss Lind, of Hageby, and other prominent anti-vivisectors. In his address, Professor Halliburton had occasion to mention the name of Lord Lister, and he was interrupted with shouts of "He's a brute!" This expression of the mind of the man in the street toward the greatest benefactor of his age is a sad example of the attitude of a large section of the public towards science and men of science. There are few countries in which so little respect is paid to knowledge and learning as England. If he lived in Berlin, for instance, or in Paris, Lister's name would be a household word, and an insult of this kind in a public assembly would meet with its fitting revenge. The great bulk of Londoners, however, are careless of the names of such men as Lister, and the mere suggestion that he had to do with scientific research was enough to call forth the expression of opinion we have quoted. It is not as if the abuse came from a Hyde Park orator, or from one of an ignorant mob. Miss Hageby's meeting was, we understand, "select," and attended by well-dressed and —save the mark!—educated people. It is some time since Arnold preached against the "Philistinism" of the British public; it has been left to our day for it to merit the word "Hooliganism."

The General Medical Council as a Court.

The Medical Defence Union has done an important service to the profession—by no means its first—in commenting strongly, in its Annual Report, on the unsuitability of the General Medical Council as a tribunal. In many cases, the Council has to act both as prosecutor and as judge, contrary to accepted principles of justice. In all cases it suffers from the unwieldiness of its constitution and the exiguity of its powers. A bench of some thirty judges, with no power to compel witnesses or to administer oaths, is hardly a convenient machine for the fulfilment of justice. Moreover, with a magnificent irresponsibility, the Council refuses to be bound by precedents, and what is evidence at one time is not evidence at another. The present position is unsatisfactory to all concerned. It ought to be possible to devise some means by which a Court, both effective and trusted, could be established to deal with penal cases, and when the reform of the General Medical Council—long overdue—arrives, the point must not be forgotten.

A Suggested Army Male Nursing Co-Operation.

There are many features of interest in the suggestion of Miss Ethel McCaul to organise a male nursing co-operation for retired orderlies on leaving the service. A good training is now given to these men in the branch of the Army Medical Service concerned, and, be it noted, at a considerable cost to the country. In the present unorganised state of male-nursing in the United Kingdom there is a considerable risk that after discharge they will find no market for their skilled labour. From an economic point of view, however, it is abundantly clear that to allow such men to drift into the ranks of the unemployed after giving up their naval and military duties is nothing short of wanton extravagance. The general dearth of male nurses was evident at the time of the South African war, when the Army Medical Department scoured the country for recruits, but for the most part had to depend upon undisciplined and often untrained men at a high rate of remuneration. The present scheme for founding a co-operative nursing association is to be commended, inasmuch as it proposes to establish an agency, which should in the course of time be self-supporting, for the benefit of a deserving class of public servants.

Report of Experiments on Animals.

The Home Office Inspector under the Experiments on Animals Act (Dr. G. D. Thane) has just issued his report for last year, and it shows that the number of experiments on animals is rising steadily. Last year there were 46,073 experiments, an increase of no less than 8,138 on the 1905 figures, the bulk of which was due to the work of the Imperial Cancer Research Fund. For the fund no less than 21,082 experiments were performed in 1906, 20,795 of them being inoculations. Indeed, the experiments performed under Table IV. (B), which shows which were performed without anæsthetics, numbered no less than 43,287, all of them being inoculations or trivial operations; in no case was a cutting operation more severe than a superficial venesection allowed to be performed without anæsthetics. Of these 43,287 experiments, many, of course, were failures, that is to say, that the animal was not infected with the injected substance, and it therefore suffered no inconvenience beyond the prick of the needle. The number of experiments done under the regulation that the animal must be kept under an anæsthetic the whole time of the operation, and killed before it comes round, was 1,588, and the number in which such subsequent killing was dispensed with for one reason or another was 1,198. So that the amount of pain actually suffered as the result of a year's "vivisection" must really have been very small indeed.

It is noticeable that nearly 6,000 experiments were performed for public bodies; 2,114 experiments were for the Royal Commission on Tuberculosis; 4,732 for the preparation of serums, and 1,079 for testing of drugs. In a word, the utility of experimental work is becoming better known and more widely recognised as years go by, and there is consequently a greater measure of public confidence accorded to its results. The anti-vivisectionists have plenty of sound and fury, but they represent a very small section of the public.

Registrar-General's Annual Summary.

It is a curious reflection that whereas among Eastern nations it was held to be peculiarly unlucky to enumerate the population, at present vital statistics are of essential importance for the purpose of learning the tendencies, weaknesses, and faults of a nation. The present Annual Summary of the Registrar-General is the fifty-third issued, each number being a little fuller and more informing than its predecessor. It is a pity that the Registrar-General relies on the old and untrustworthy method of estimating the population during an intercensal period, namely, that of assuming a similar average annual increase as during the last completed period. Surely he has the exact figures of births, deaths, immigrations, and emigrations. However, assuming the old ratio, the population of England and Wales is reckoned to be 34,547,016, of which 16,689,707 are males, and 17,857,309 females. During 1906 there were 269,734 marriages, giving a rate of 15.6 persons per 1,000 of the population; this was 0.3 per 1,000 above the corresponding rate in 1905, but 0.2 below the rate for the preceding ten years. The birth-rate was 27.0 per 1,000, giving a rate 0.2 below 1905, 1.7 below that for the previous ten years, and, altogether, the lowest rate on record for any year. The deaths on the other hand numbered only 15.4 per 1,000 of the population, which, though 0.2 above the rate for 1905, was 1.4 below the rate for 1896-1905. The infantile mortality was 133 per 1,000 registered births, also a decrease of 5 per 1,000, as compared with 1905, and 14 below the preceding ten years' average. A similar story is told throughout the report, and these figures are the best proof that the sense of national responsibility is rising, and that the population is tending to regulate its life by intellectual rather than animal standards.

PERSONAL.

THEIR MAJESTIES THE KING AND QUEEN will receive the delegates to the International Red Cross Conference at Buckingham Palace on June 15th.

HIS MAJESTY THE KING received at a special Levee on Monday last, the following medical veterans, who were present at the Indian Mutiny campaign fifty years ago:—Surgeon-Generals Sir J. H. K. Innes; J. Corbyn, J. Fairweather, C. A. Innes, and C. Kilkelly.

SIR ARTHUR RUCKER, M.A., D.Sc., LL.D., F.R.S., Principal of the University of London, will distribute the prizes to the successful students at Guy's Hospital, on Thursday, July 4th next. The usual garden party will be given in the grounds.

THE Cavendish Lecture of the West London Medico-Chirurgical Society will be delivered on Friday, June 21st, in the Kensington Town Hall by Mr. C. B. Keetley, F.R.C.S., the subject being "The Question of Preserving or Sacrificing Parts and their Functions."

DR. N. H. CHOKSEY, whose name is known in connection with plague-research in Bombay, at the fourth annual meeting of the American Society of Tropical Medicine, was elected an honorary member of the Society.

WE learn with great regret that John R. Kissinger, one of the two United States Hospital orderlies who submitted himself for experiment with yellow fever mosquitoes, is very ill with myelitis, the result of the infection. He is still under thirty years of age.

MAJOR H. HERBERT, I.M.S., whose name is well-known in connection with cataract extraction, is leaving India for England.

WE regret to announce that Dr. D. B. Lees is retiring from the active staff of St. Mary's Hospital, having been physician to that institution for twenty years. In accordance with precedent Dr. Lees will retain his connection with St. Mary's Hospital as a member of the consulting staff.

DR. H. A. CALEY has been elected to the vacancy caused by the retirement of Dr. Lees. He has served eleven years as assistant physician with charge of out-patients at St. Mary's Hospital.

SIR PATRICK MANSON, medical adviser to the Colonial Office, has been selected for the position of medical attendant to the King of Siam during the latter's forthcoming visit to this country.

THE Secretary of State for India has appointed Sir R. Havelock Charles to represent India at the Red Cross Conference.

AT a meeting of the Corporation of the City of London held at Guildhall last week, it was resolved to present the freedom of the City to Lord Lister in a gold box, in recognition of his eminence as a surgeon and the invaluable services he had rendered to humanity by the discovery of the antiseptic system.

SIR CHARLES LAMBERT ORMSBY, late President R.C.S. Ireland, and Mr. F. Conway Dwyer, Fellow and Examiner in Surgery, R.C.S. Ireland, have been appointed assistant examiners in surgery to the Apothecaries' Hall, Dublin, vice Sir Henry Howse and Mr. Alexis Thomson, retired.

THE annual dinner of the Indian Medical Service will be held at the New Gaiety Restaurant, London, on Thursday, June 13th, at 7.45 p.m., when Surgeon-General Sir Benjamin Franklin, K.C.I.E., will preside. Officers intending to be present should communicate with the honorary secretary, Lieutenant-Colonel P. J. Freyer, 27 Harley-street, London, W.

THE degree of Doctor of Medicine has been conferred upon Dr. Wilfred T. Grenfell, C.M.G., by the University of Oxford, in recognition of the work he has achieved in improving the social condition of the Labrador fisherfolk. This is the first honorary M.D. degree conferred at Oxford. Dr. Grenfell was educated at Queen's College, Oxford, and obtained his "Blue" for Rugby football. Afterwards he studied at the London Hospital and was house surgeon to Sir Frederick Treves. During the fifteen years he has been in Labrador he has established four hospitals.

A Clinical Lecture
ON
DEVELOPMENTS AND DANGERS OF EXTRA-UTERINE PREGNANCY (*a*).

By ARTHUR E. GILES, M.D., B.Sc. Lond., F.R.C.S. Ed.,

Surgeon to the Chelsea Hospital for Women; Gynæcologist to the Prince of Wales's General Hospital, Tottenham.

The history of our knowledge of the subject of extra-uterine pregnancy is one of the most striking in the whole range of gynæcology. From some of the trees of knowledge science would seem to be content to pluck a fruit now and then, perhaps even at long intervals; but here, one might think that in a frenzy of ardour, perhaps impelled by a prophetic intuition that the time was fully ripe, she had seized and shaken the trunk and lost no time in gathering and tasting the abundant fruit.

Twenty-five years ago the subject of extra-uterine pregnancy was hardly touched upon in gynæcological text-books, except unconsciously, when the condition known as "hæmatocele" was described. I say unconsciously, because, though extra-uterine pregnancy was mentioned as a possible cause of hæmatocele, it was mentioned without much conviction, apparently in the same spirit as that displayed by a candidate at an examination who is determined to leave out nothing that has even a remote bearing on the subject. Knowing, as we do now, that a hæmatocele arising independently of extra-uterine pregnancy is very rare, the progress made in these twenty-five years is strikingly brought home to us when we find that in the text-books of that period extra-uterine pregnancy is mentioned, along with ovarian tumours, pelvic cellulitis, etc., as one of the conditions to be differentiated from a hæmatocele. The explanation is, of course, simple; the significance of the mole, and the value of the microscopical demonstration of chorionic villi as evidences of pregnancy were unknown; and an extra-uterine pregnancy was recognised as such only when a fœtus was found. Up to twenty-five years ago, an operation for intraperitoneal hæmorrhage occasioned by rupture of a gravid tube had never been undertaken, although it had been recommended. Taylor (*b*) quotes a striking passage from Parry's work, written in 1876:—"From the middle of the eleventh century, when Albucasis described the first known case of extra-uterine pregnancy, men have doubtless watched the life ebb rapidly from the pale victim of this accident as the torrent of blood is poured into the abdominal cavity, but have never raised a hand to help her. Surely this is an anomaly, and it has no parallel in the whole history of human injuries. The fact seems incredible, for if one life is saved by active interference it may be triumphantly pointed to as the first and only instance of the kind on record. In the whole domain of surgery —for we cannot look to other than surgical measures under the circumstances—there is now left no field like this. . . . The only remedy that can be proposed to rescue a woman under these unfortunate circumstances is gastrotomy—to open the abdomen, tie the bleeding vessels, or to remove the sac entire."

When surgery at length responded to the urgent appeal of the dying woman, the results were far-reaching, for not only were many women brought back to life whose feet were already cold with the waters of the river of death, but pathology hastened to follow where surgery had led the way; and most—we might almost say the whole—of our knowledge of early extra-uterine pregnancy was gained by this means. I cannot stay now to trace the evolution of that knowledge; let it suffice that I recall two names that stand out prominently on the roll of honour. It was Lawson Tait who had the courage to take up the challenge of Parry, and performed in 1883 the first operation deliberately undertaken for tubal rupture; to his initiative thousands of women owe the saving of their lives; whilst to Bland-Sutton our profession is chiefly indebted for the advancement of our knowledge of these conditions, by his work on the Tubal Mole and Tubal Abortion, and by his demonstration that the chorionic villi afford us a certain test of the presence of extra-uterine pregnancy.

I must now pass on to the consideration of my more immediate subject—the Developments and Dangers of Extra-Uterine Pregnancy. There are two forms of extra-uterine pregnancy, ovarian and tubal. There are two other interesting varieties found, namely, *interstitial* or *tubo-uterine*, where the pregnancy is neither frankly in the uterus nor frankly outside it, and runs a course whose striking characteristic is a particularly dangerous form of rupture; and *pregnancy in the undeveloped horn of a uterus unicornis*, where the pregnancy is properly speaking intra-uterine, but runs a course similar to that of a tubal pregnancy.

Ovarian pregnancy is a very rare condition, the very existence of which has been established beyond dispute only within the last ten years. I shall therefore restrict my observations to the subject of *tubal pregnancy*, which I propose to deal with on the same lines as those followed in an earlier communication (*c*); that is, I shall take a tubal pregnancy from its beginning and trace its possible developments with special reference to their clinical aspects. The following table, taken from my previous paper, will serve as the text of my remarks.

Table to Illustrate Developments and Dangers of Extra-Uterine Pregnancy.

Course of Extra-Uterine Pregnancy.

1. Early tubal rupture (third to sixth week). Fœtus perishes.
2. Tubal abortion (sixth to eighth week). Fœtus perishes.
3. Later tubal rupture (sixth to twelfth week).
    - (I.) Primary intra-peritoneal rupture.
        - (*a*) Fœtus perishes.
        - (*b*) Fœtus survives and goes on as abdominal pregnancy to term.
    - (II.) Intra-ligamentary rupture.
        - (*a*) Fœtus perishes.
        - (*b*) Fœtus survives.
            - (*a*) Mesometric pregnancy goes on to term.
            - (*b*) Secondary intra-peritoneal rupture.
                - (i.) Fœtus perishes.
                - (ii.) Secondary abdominal pregnancy goes on to term.

We suppose, then, that a fertilised ovum (oösperm) is arrested on its way to the uterus and becomes engrafted in the Fallopian tube. Making the most of the slender resources at its disposal, it proceeds to form a placenta; for this purpose the rather indifferent decidua supplied by the tube is utilised. So poor is this decidua at first, that Clarence Webster's discovery of its presence was for a long time questioned by other competent observers; but it is now generally

---

(*a*) A Clinical Lecture delivered at the London Post-Graduate College, January 23rd, 1907.

(*b*) "Extra-Uterine Pregnancy," by J. W. Taylor, London, 1899, p. 2.

(*c*) Clinical Journal, December 28th, 1904.

conceded that Webster's theory is correct. The symptoms that are so characteristic of intra-uterine pregnancy are not always present with tubal gestation; morning sickness is usually absent and menstruation is not always arrested. In the minority of cases, however, an extra-uterine pregnancy may proceed to full term without any suspicion being raised in the mind either of the patient or her doctor that it is not a normal pregnancy. Some authorities believe that it is possible for a tube to carry a fœtus to term without rupturing at all; but I believe that a case in which this occurrence is incontrovertibly proved has yet to be described. It is certain that this course is at least very rare; as a general rule the career of an extra-uterine ovum is marked by greater vicissitudes than are even found in the proverbial course of true love. We shall now consider these accidents in the order of their occurrence.

(1) *Early Tubal Rupture.*—By this is meant a rupture taking place between the third and sixth week of pregnancy. The cause of the accident is almost invariably the occurrence of hæmorrhage in the ovum, between the chorion and the amnion. The blood is of fœtal origin, as is proved by the presence of nucleated red corpuscles. As the result of this hæmorrhage the ovum rapidly increases in size, and if it be situated in a part of the tube that is not adapted to rapid expansion, the inevitable result is rupture of the tube, associated with free hæmorrhage (this time maternal blood) into the peritoneal cavity. We shall see presently that later rupture frequently takes place into the broad ligament; but in the early days the broad ligament has not been sufficiently expanded to allow of this (Fig. 1), and so the rupture is invariably intraperitoneal. By the end of the second month the broad ligament has expanded (Fig. 2.), so that an intraligamentary rupture becomes possible, as we shall see later. Another important characteristic of early rupture is that the bleeding is always profuse, and consequently does not become limited in the form of hæmatocele, as may occur with the later rupture.

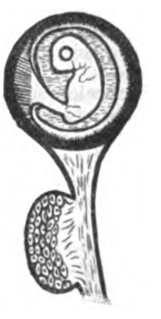

FIG. 1. — Diagrammatic transverse section of a gravid tube at the end of the first month.

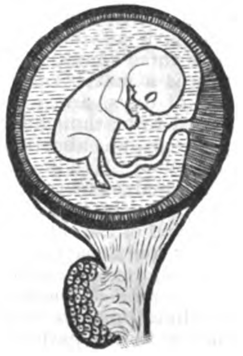

FIG. 2.—Diagrammatic transverse section of a gravid tube at the end of the second month.

The clinical picture of such a case is therefore that a patient who has perhaps gone beyond the usual time for menstruation by only a week or two, and may in fact not even be overdue, is suddenly seized with marked collapse and faintness, perhaps associated with some pain on one side. She rallies very little if at all, and very soon presents all the signs of internal hæmorrhage—deathly pallor, a weak, thready, rapid pulse, subnormal temperature, coldness of the extremities, sighing respiration and a sense of impending death. Untreated, these cases represent the most appallingly sudden disaster that may happen to an apparently healthy woman; but when treated by prompt surgical intervention, they represent the most signal triumphs of surgery, for the patient is obviously brought back to life from the very verge of death.

These cases make us realise the burden of responsibility which, like some "old man of the sea," sits for ever on our shoulders, though we may at times forget its presence. For the life or death of the patient is determined within twenty-four hours of the rupture; and which of the two it will be depends on whether or not a prompt diagnosis is arrived at. Fortunately diagnosis is here relatively simple; the sledge-hammer blow that brings a healthy woman down to the lowest ebb can be brought about by nothing else that presents at all similar characteristics to a ruptured gravid tube; perhaps the nearest approach to it is a perforated gastric ulcer, and that has many distinguishing features. But even if the diagnosis between these two were difficult, it would matter the less since the treatment is the same in either case, namely, the opening of the abdomen at the earliest possible moment.

The cause of early rupture is not well understood. Taylor states that it is often associated with pregnancy in the uterine end of an atrophic or ill-developed tube. We will now suppose that this early danger is escaped, and that the pregnancy goes on developing until the eighth or tenth week. Is a diagnosis possible at this stage, before further troubles arise? It is possible in certain cases. For example, if a patient has gone eight or ten weeks without menstruating, and presents symptoms of pregnancy, but complains of one-sided pain, and an examination is made, and the uterus is hardly larger than a normal unimpregnated uterus, whilst the tube on the side to which the pain is referred is felt considerably enlarged, then a diagnosis of unruptured tubal pregnancy would be justified. We may note in passing that the swelling produced by an unruptured gravid tube is nearly always mobile and free; whilst the swelling that results from tubal rupture or abortion is nearly always fixed. Perhaps the chief reason why a diagnosis is not usually made at this stage is that no abnormal symptoms may be present, and consequently an examination is not made. A difficulty in diagnosis might arise if an early intra-uterine pregnancy were associated with a small ovarian cyst or a swelling of the tube such as a hydrosalpinx or a new growth. But I am certain that when symptoms of pregnancy co-exist with a swelling on one side of the uterus, a diagnosis of extra-uterine pregnancy is praiseworthy, even if it should turn out to be incorrect.

Pursuing our study of the destinies of the tubal embryo, we find that at some stage from six to ten weeks the ovum may be converted into what Mr. Bland-Sutton has called a "tubal mole," by hæmorrhage taking place between the chorion and amnion, as previously described. This paves the way for an accident known as "tubal abortion."

(2) *Tubal Abortion.*—It is well known that a cause of uterine miscarriage is the conversion of the ovum into a "mole;" hæmorrhage occurs, and continues until the mole has been expelled. A parallel course of events may take place in the gravid tube; and if the fimbriated end of the tube has remained open, the mole may be expelled into the peritoneal cavity; the bleeding may then cease, the tube returns to its normal calibre, and after a few days' disturbance the patient gets all right again. This, however, is not the usual history. More often the mole remains partly attached, and so bleeding goes on until the patient succumbs or is relieved by operation. Bleeding from an unruptured tube is seldom profuse and cataclysmic, as it is when the tube ruptures; it is usually gradual, and may amount to little more than what Taylor calls a "blood-drip." In that case, as the blood collects round the open end of the tube, it tends to become encapsuled, probably owing to the setting up of a mild localised peritonitis. Such an encapsuled collection of blood round the open end of a tube is called a *peritubal hæmatocele* (Fig. 7). The hæmatocele becomes gradually larger, owing to the outpouring of fresh blood into its centre; in a case that goes on for days or weeks, the peripheral part of the blood becomes coagulated in layers, producing an appearance similar to that found in a sacculated aneurysm. Sometimes a curious phenomenon is observed: if the ovum be situated near the

tubal isthmus, blood may collect in the outer half of the tube and become partly coagulated; this is expelled into the peritoneal cavity, and a second collection of blood forms and is expelled. This process may continue for some time. On opening the abdomen one of these clots may easily be mistaken for the mole; the presence of several will reveal their true character, and the mole itself will be found within the tube. When tubal abortion occurs or threatens, hæmorrhage from the uterus takes place; this is due in some cases to reflux of blood from the tube into the uterus, and in such a case the bleeding may be fairly free; but it may be due to disintegration and gradual expulsion of the uterine decidua, and then the bleeding takes the form of a rather scanty brownish discharge.

The clinical picture presented by such a case is therefore as follows:—A patient who has gone two or three weeks over the time for menstruation has a little hæmorrhage, which she may regard as a delayed period. But the bleeding continues, perhaps for weeks, seldom profuse, but scanty, dark, or perhaps as a mere brownish discharge, intermixed with decidual fragments.

There may be no pain at all, or there may be pain of varying severity, referred to one side. On examination the uterus is little if at all enlarged; on one side and behind it is a rather soft, doughy, or boggy swelling. Neither the symptoms alone nor the physical signs alone are sufficient for a diagnosis; but when they are present together, the diagnosis can hardly be missed.

It is a noteworthy fact that in many of the stages of extra-uterine pregnancy a diagnosis cannot be made on physical signs alone, because there are other pelvic conditions which cause very similar signs; and so the diagnosis comes to depend largely on the history and symptoms, the value of the physical signs being that they confirm, or at least are not inconsistent with, the deductions drawn from the history of the case.

The fœtus invariably perishes when either early rupture or abortion occurs; we might almost describe it as suicide, because the accident in these early days is almost invariably of fœtal origin, that is to say, it is brought about by hæmorrhage into the ovum and the formation of a mole; and the disturbance in the tube, whether it takes the form of rupture or abortion, is brought about by the sudden increase in the size of the ovum.

(3) *Later Tubal Rupture.*—If a tubal ovum survives the obstacles to its development which have just been enumerated, it reaches another and even more critical period, that of the tenth to the twelfth week. I say "more critical" because, while the earlier dangers may be avoided, this one must be faced, for no tube can go longer than three months without rupture.

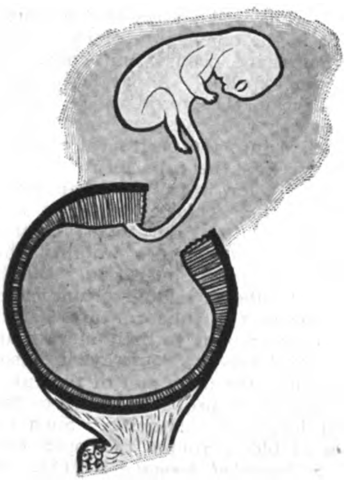

FIG 3.—Intra-peritoneal rupture; placenta uppermost; hæmorrhage; the fœtus perishes.

To this general statement there are only two exceptions: First, those very rare and even doubtful cases in which the pregnancy goes to term in an unruptured tube; and, secondly, those rare instances in which a late abortion occurs. Of this there is only one case that I know of on record, described by Cullingworth and Fairbairn.

When the ovum has reached the age of three months, the broad ligament has become sufficiently stretched to allow of two possibilities in the direction of the rupture, namely, intra-peritoneal and intra-ligamentary. Into each of these divisions the position of the placenta introduces two sub-divisions, in one of which the fœtus necessarily perishes, whilst in the other it may survive (see Figs. 3–6).

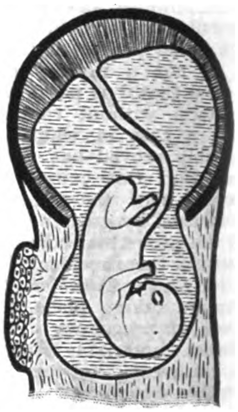

FIG. 6.—Intra-ligamentary rupture; placenta uppermost; the fœtus survives.

I.—*Primary Intra-peritoneal Rupture.*—(*a*) If the placenta lies in such a position that it is involved in the rupture of the tube, or the amnion is broken, the fœtus perishes, and severe intra-peritoneal bleeding takes place (Fig. 3). This bleeding is seldom quite so desperate as it is in early rupture; for while in early rupture the mother seldom survives unless operated on within twenty-four hours, in the later rupture the bleeding may be sufficiently gradual to give two or three days' grace. But I should advise no one to rely on these extra days if an intra-peritoneal rupture is diagnosed. On the other hand, the bleeding is more rapid than it is in cases of tubal abortion, and the shock and collapse are proportionately greater. Later intra-peritoneal rupture thus occupies a somewhat intermediate position between early rupture and abortion. Without pretending to precise accuracy, but to give an impression of the relative severity of these three conditions we may say that while early rupture is a matter of hours, later rupture may be a matter of days, and abortion of weeks.

It used to be thought that a hæmatocele could only result from an abortion; but it has been shown, especially by Handley, that a rupture may cause such gradual hæmorrhage that there is time for encapsulation. In this case the clot does not surround the free end of the tube as it does in peritubal hæmatocele, but only partially surrounds the tube in its course, and Handley therefore gave it the appropriate name of *paratubal hæmatocele* (compare Figs. 7 and 8).

The clinical picture of a case of later intra-peritoneal rupture is that a patient who thinks herself between two and three months pregnant is suddenly seized with faintness, frequently accompanied by pain, as if something had given way inside her. She may be doing something involving some exertion; one patient I saw was stooping down to do something in the garden, but the rupture may occur when the patient is lying quietly in bed. By degrees she gets weaker and fainter, presenting, sometimes sooner, sometimes later, all the signs of severe internal hæmorrhage. On examination there may be a sense of fulness and resistance in the pelvis and lower abdomen, if the bleeding has been going on for some time; vaginal examination generally shows a definite swelling on one side of the uterus, due to the enlarged tube; and the pouch of Douglas gives the sensation of obscure resistance produced by an accumulation of thick fluid. It is hardly possible to mistake the nature of the condition, if only its possibility be borne in mind.

(*b*) If the placenta occupies such a position that it is not involved in the rupture of the tube, and the amnion remains unbroken, the fœtus, enveloped in the amnion may pass into the peritoneal cavity, and continue its development without interruption (Fig. 4). This is a *primary abdominal pregnancy*. It is a noteworthy fact that a primary abdominal pregnancy cannot occur as the result of the dropping of a fertilised ovum into the peritoneal cavity in the first instance; if the placenta cannot have the uterine decidua in which to develop it must have a tubal decidua; so that an abdominal pregnancy must pass through the stage of a tubal pregnancy.

II.—*Intra-ligamentary Rupture.*—We have seen that this accident cannot occur very early, because the broad ligament is not sufficiently expanded to permit of its taking place. It is specially prone to occur about the tenth to the twelfth week. It is a noteworthy fact that nearly all the difficulties that lead to a wrong diagnosis in tubal pregnancy centre round this form of rupture. The position of the placenta in relation to the rent in the tube gives us two possibilities in the sequence of events.

(*a*) When the placenta lies over the broad ligament it is involved in the rent; hæmorrhage takes place, and the fœtus perishes (Fig. 5). The bleeding is usually less severe than in any other form of rupture, because the layers of the broad ligament provide a ready-made capsule by means of which the amount of bleeding is restricted. The resulting blood-tumour in the broad ligament is properly a "hæmatocele" (Fig. 9), although this term is usually restricted to an encysted collection of blood in the peritoneal cavity. Broad ligament hæmatocele is usually called a "hæmatoma." Owing to the anatomical restriction of the bleeding in these cases, the symptoms are seldom very pronounced. There is usually an attack of faintness, which may be so slight that the patient lies down for a few hours and then gets up feeling comparatively well. Very soon there is a slight "show" from the vagina, due to the commencing disintegration of the uterine decidua. This may go on for weeks or even months, in the form of a brownish discharge. The patient and her medical attendant may both think that she is in for a miscarriage. There are three important things that should put the medical attendant on his guard and lead him at least to suspect the true state of things. The first is the slight syncopal attack, which may be repeated; the second is the complaint of pain on one side, which is nearly always present; the third is the complaint of a scanty brownish discharge; and when an examination is made, as should invariably be done in the presence of these symptoms, a swelling other than the uterus is felt in the pelvis, showing at any rate that we have not to do with a case of ordinary miscarriage.

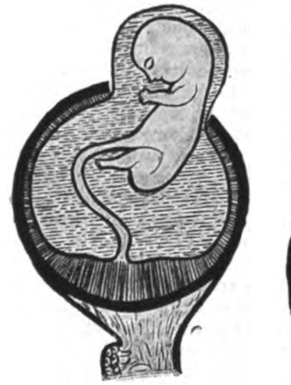

FIG. 4—Intra-peritoneal rupture; placenta below; the fœtus may survive.

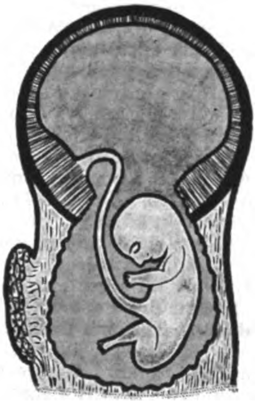

FIG.* 5.—Intra-ligamentary rupture; placenta below; hæmorrhage; the fœtus perishes.

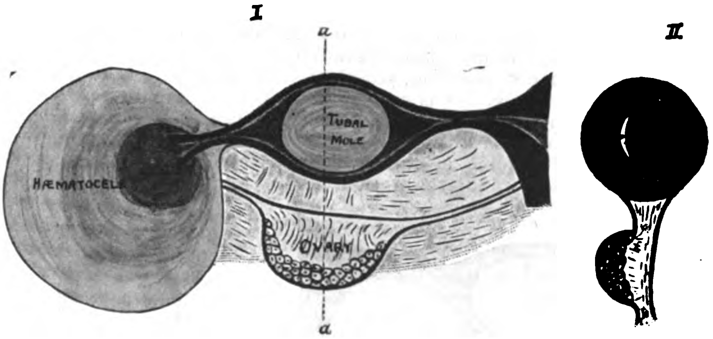

FIG. 7.—A peri-tubal hæmotocele. In this and the two following figures, 1 is a longitudinal section, and 2 is a transverse section through a.a.

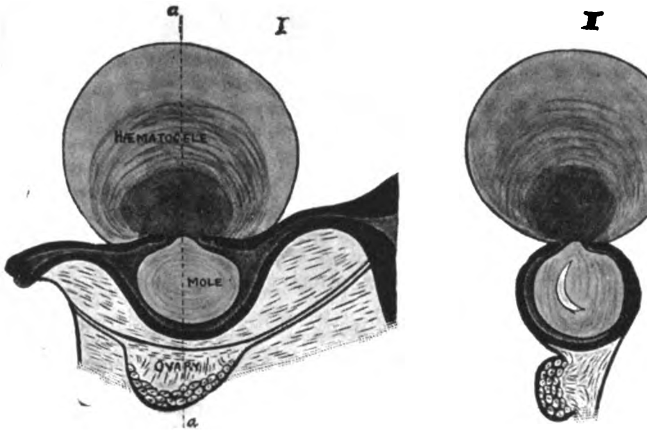

FIG. 8.—A paratubal hæmatocele.

When the bulk of the swelling is situated behind the uterus, as sometimes happens, the uterus is pushed up and the cervix is pressed against the pubes; and as it may be difficult to differentiate the body of the uterus from the rest of the swelling the condition may closely simulate retroversion of the gravid uterus, particularly because in both cases there is retention of urine. A useful distinguishing feature is the doughy feeling imparted to the examining finger by the sac and effused clots in the pouch of Douglas, contrasting with the tense elastic feeling of the retroverted gravid uterus.

Chronic inflammatory disease of the appendages often presents such a striking resemblance to the form of tubal pregnancy we are now considering, that it is impossible to distinguish between them. This is more particularly the case when inflammatory disease affects one side. With both conditions there is lateral pain, with or without rise of temperature; and a fixed tender swelling is found by the side of the uterus. We have then nothing but the history of amenorrhœa to clearly distinguish tubal pregnancy; and as menstruation may be uninterrupted in this condition, and may be irregular or profuse with tubal disease, mistakes may easily arise.

(*b*) When the placenta is situated in the upper part of the circumference of the tube, and the rent takes place on the broad ligament side, as in Fig. 6, the pregnancy may continue uninterrupted as a mesometric pregnancy. But even now the possibility of other vicissitudes is not yet over. After a mesometric pregnancy has gone on for a month or two, a secondary intra-peritoneal rupture may take place with two final possibilities: (i.) The fœtus perishes, probably because the rent involves the placenta or its blood-supply, in much the same way as with primary intra-peritoneal rupture; but it would appear that this is a very rare accident, because it is a very exceptional thing for a patient to be seized with severe intra-peritoneal hæmorrhage later than the fourth or fifth month of extra-uterine pregnancy. Probably the more common occurrence, when secondary intra-peritoneal rupture takes place, is for the fœtus to continue developing, this being a secondary abdominal pregnancy. It is easy to surmise a reason for this. As the broad ligament expands, it becomes thinned out; and if rupture takes place the rent is more likely to involve a non-vascular part of the thinned-out membrane than the fleshy placenta.

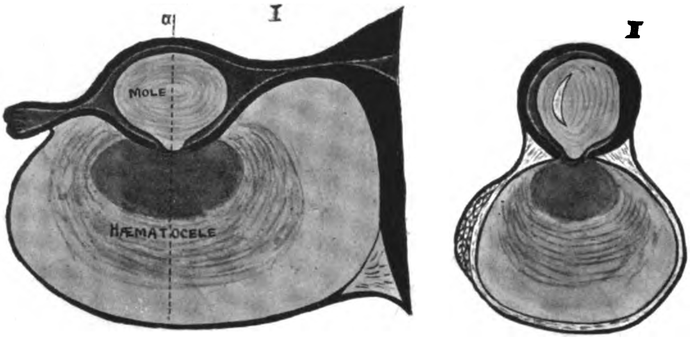

FIG. 9.—A broad ligament hæmatocele (hæmatoma).

It will be seen that an extra-uterine pregnancy may go on to full term in one of four distinct ways:—

(1) By the development of the pregnancy in an unruptured tube.

(2) By the development of a primary abdominal pregnancy.

(3) By the development of a primary intra-ligamentary pregnancy.

(4) By the development of a secondary abdominal pregnancy.

In the last case the fœtus must survive two ruptures, the first of the tube into the broad ligament, and the second of the broad ligament into the peritoneal cavity.

The phenomena of extra-uterine pregnancy at full term forms too large a subject, however, to be dealt with here.

NOTE.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by Samuel West, M.D. Oxon., F.R. C.P. Lond., Physician to and Lecturer on the Principles and Practice of Medicine at St. Bartholomew's Hospital. Subject: "Foods and Feeding in Certain Conditions."*

ORIGINAL PAPERS.

ON THE EXAMINATION OF THE URETHRA AND BLADDER BY THE ELECTRIC LIGHT. (*a*)

By ANDREW FULLERTON, M.D., F.R.C.S.,

Hon. Assistant-Surgeon to the Royal Victoria Hospital and to the Belfast Hospital for Sick Children.

PART II.—(*Conclusion.*)

To use the cystoscope, pass the instrument like a bladder sound, and, turning down the beak, examine the most important area, namely, the trigone. Its base is formed by the interureteric bar, at the extremities of which, the openings of the ureters can be seen as small slits acting rhythmically. Having examined carefully this triangular area, every portion of the bladder-wall must be systematically inspected. A bubble of air is usually seen at the apex or highest point of the bladder when the beak of the instrument points upward. It serves as a landmark for localising abnormal appearances.

The neck of the bladder is not easily seen with the ordinary cystoscope. Newman, of Glasgow, has suggested a modified prism for this purpose. The rays of light are reflected at an acute angle, so that objects situated in front of the prism are more readily seen. On applying for this instrument to the makers I was informed that some improvements in it were being effected, so that I am unable to speak personally as to its advantages.

Returning to the ureteral openings, it is necessary to carefully note the following points: Their position, size, shape, colour, movements, efflux, and surroundings. For instance, instead of being slit-like, they may be slipper-shaped, oval, round, patulous, elongated, or contracted. They may be retracted, protruded, or prolapsed. They may be closely surrounded by blood-vessels, or they may open in an area comparatively scantily supplied therewith. Let me illustrate my meaning by referring to a few cases. In No. 46, examined seven weeks after suprapubic prostatectomy, the left ureteric orifice was seen to be oval and dilated, the result of back pressure from the enlarged prostate. In Case 28, a boy, æt. 5, they were slipper shaped—that is to say, the inner margin was depressed so as to form an orifice like the fenestra ovalis of the heart. This appearance denotes the first stage in dilatation, due, in the case of this boy, to a stone which blocked the internal orifice of the urethra during micturition, causing more or less back pressure. In Case 44, the left orifice was round and contracted, possibly due to a previous attack of pyelitis on that side. In Case 102, to which I shall again refer, the right orifice was dilated and surrounded by numerous minute vessels. Urine containing pus and tubercle bacilli was obtained from this ureter. The orifice of the opposite ureter was slit-like and normal. In Case 2, sent by Dr. Mackenzie, a male, æt. 53, who had just had an attack of right-sided renal colic, the lips of the right ureteric orifice were swollen and red, and a small stone lay free on the posterior bladder-wall. In Case 79, a man, æt. 36, suffering from symptomless hæmaturia, well-marked vascular twigs were seen radiating from the left ureteric orifice, and, as might be expected, the blood issued from that side. Increased vascularity round the ureteric orifice denotes a similar condition of the pelvis of the corresponding kidney. In Case 88, a man, æt. 29, suffering from pyuria, the right ureteric orifice was surrounded for a considerable area by clusters of closely set, cystic-looking bodies resembling minute red currants. These were due to the irritating effects of pus-containing urine from the kidney of that side. The urine from the opposite side was clear. These few examples will serve to emphasize the importance of carefully noting the appearance of the openings. At the same time, the diastole and systole of the ureteric orifice should be watched for a few seconds, and any departure from the normal noted. Just before the efflux, one can see a wave of peristalsis pass from without inwards in the line of the ureter. When the wave reaches the orifice, the latter opens and a jet of fluid issues. The opening then contracts till it is almost, if not quite, invisible, and then gradually resumes the position of rest. The character of the efflux must be carefully examined. In this way blood and pus may be seen to be ejected from one or both ureters, thus determining the organ affected, as I hope to show in my subsequent remarks. In Case 110, seen with Dr. Hicks, there was a swelling in the right kidney region. *No* urine could be obtained from the right orifice, and the catheter was arrested 7 ins. up, indicating, possibly, a block in the form, probably, of a kink or a stone.

Let me draw attention here to a very rare source of fallacy. Through the kindness of Professor Symington and Dr. Lowry, of the Anatomical Department of Queen's College, I was allowed during the present session to examine a case of single kidney in a dissecting-room subject. The body was that of a female, æt. 18. The left kidney was absent. On the right side, a large conglomerate mass represented both

---

(*a*) Being a Paper Read before the Ulster Medical Society on February 28th, 1907.

kidneys. There were two fairly marked lobes with an intervening portion, the whole mass being provided with three arteries, three veins, and two ureters. The dimensions were 5¾ ins. by 3¾ ins. by 1½ ins. The organ was saddle-shaped and was situated as follows: The upper portion lay for the most part in the right iliac fossa at the inner margin of which the lower pole was curved on the upper to almost a right angle, the inferior extremity of the organ dipping down into the pelvis. The deep surface of the organ was closely applied to the posterior abdominal wall, and the outer wall of the true pelvis. There were two ureters, both arising from the anterior surface, the longer and thicker from near the upper pole, the shorter and narrower from near the lower pole. Both ran directly downwards, the larger to the right and the shorter to the left, to open at the usual situation of entry at the trigone of the bladder. I had the curiosity to cystoscope the bladder distended with water. The examination would have led me to suppose that there were two kidneys with the usual separate ureteral openings into the bladder. Both orifices were slit-like and normal in position. The right opening appeared to be about twice as long as the left, and longer than normal. The inter-ureteric bar was more pronounced on the right side. I need hardly point out what complications such an abnormality would give rise to in the matter of diagnosis, should it be found necessary to deal surgically with such a case. Fortunately the occurrence is rare—once in 10,000 bodies, according to MacDonald Brown (*Journal of Anatomy and Physiology*, Vol. XXVIII).

Having dealt generally with the examination of the bladder and ureteric orifices, I now propose to utilize the cases examined during the last year to illustrate some of the various abnormal changes which the cystoscope may be relied upon to disclose. In this way many of the uses of cystoscopy can be most clearly demonstrated. To do so, I have thought it well to take some of the main symptoms of urinary disease and select from my list examples to illustrate them. I will therefore discuss the cases under the following headings: (1) Those in which hæmaturia has been the chief symptom. (2) Those in which pyuria has been the chief symptom. (3) Those in which frequency of micturition has been the chief symptom; and (4) Those who have complained of a group of symptoms commonly found in cystitis, namely, pain, most commonly at the point of the penis, frequency of micturition, and the presence in the urine of pus or blood or both.

I. *Hæmaturia.*—In many cases of hæmaturia there is great difficulty in deciding the cause and site of the hæmorrhage as the following instances will show. Case 79, already briefly referred to, a male, æt. 36, had passed blood in his urine off and on for four years. The quantity was never very much, and the colour of the urine was sometimes red and sometimes darker in colour. He had been twice in the Royal Victoria Hospital. Professor Lindsay, under whose care he was on the last occasion, examined him carefully, but could find no clue as to the site of the bleeding. Radiography was tried with an unsuccessful result. Finally, the aid of the cystoscope was invoked. On December 3rd, 1906, I examined his bladder, when blood was seen to issue in vigorous jets, mixed with urine, from the orifice of the left ureter. On December 20th, I removed a small spicule of oxalate of lime calculus, which was found sticking in the parenchyma of the kidney of the left side. All bleeding ceased and he left the hospital in three weeks apparently cured. Case 83, a private patient, seen with Professor Lindsay and Dr. Sugars. A male, æt. 42, had had symptomless hæmaturia for about fifteen months. There was no indication whatever as to the site of the hæmorrhage, except perhaps the presence of crystals of oxalate of lime in his urine. I cystoscoped him on December 10th 1906, and thought that the efflux from the right orifice was slightly tinged. To make sure, both ureters were catheterized. The specimen from the right contained blood in small quantity. That from the left was normal. An exploratory operation on the right side was suggested. This has not yet been carried out. Case 96, seen with Mr. Mitchell at the Royal Victoria Hospital, was almost exactly similar. In this patient, a male, æt. 53, urine mixed with a considerable quantity of blood was seen to issue from left ureteric orifice. Clear urine issued from the right. The symptoms had lasted five weeks before his admission. He also awaits an exploratory operation. In these three cases the only symptom was hæmaturia, the urine contained no casts, and there was no pain anywhere.

Case 105, sent by Dr. Darling, is very interesting. A boy, æt. 19, had had hæmaturia, with no other sign except a slight puffiness of lower eyelids, for eight weeks. With the cystoscope, blood-stained urine could be seen issuing from both ureters. That from the left was darker in colour. In the specimens obtained by separately catheterizing both ureters, numerous casts, especially granular and epithelial, were seen by the microscope. Albumen was present in greater quantity than could be accounted for by the blood. The urine began to clear a few days after I saw him. He took an attack of influenza, however, and blood again appeared. The urine on February 16th was markedly blood-stained, specific gravity 1010, 66 ozs. in the twenty-four hours. Hæmaturia from both kidneys is rare, except of course in acute Bright's disease. There can be no doubt, I think, that this boy is suffering from a form of nephritis. Case 107, seen with Professor Lindsay and Dr. John Campbell, may be here cited. A young lady began three years ago to have attacks of hæmaturia, which was so free at one time as to threaten her life. At this time, Dr. Campbell found a large, easily palpable kidney on the right side. This attack, however, passed off, and the patient remained free for about two years, when she again began to bleed. It was now noticed that the right kidney had diminished in size, while the left had increased. In January of this year she had the last attack and in February 7th, I was asked to cystoscope her. Blood-stained urine was seen issuing from the right ureter, the orifice of which had running up to it a number of well-marked vascular twigs. The flow from the left side was normal in appearance. It was decided, however, to catheterize the ureters. Blood was obtained from the right and albuminous urine from the left. The opinion was expressed, therefore, that both kidneys were diseased. In view, however, of the risk of the patient bleeding to death it was decided to explore the side from which the hæmorrhage was coming. Accordingly on February 10th, 1907, Dr. Campbell cut down in the right side and found a kidney riddled with cysts. The kidney was removed in the forlorn hope of saving the patient, but the other being insufficient, the patient rapidly sank and died about ten days later from œdema of the glottis. Before death the left kidney began to bleed. While the result in this case is deplorable, it serves to illustrate the immense value of catheterization of the ureters even when apparently healthy urine is seen to issue from an orifice. Case 101, sent by Dr. Clokey, a male, æt. 24, an ex-soldier, was in good health until he went to South Africa in 1901. Nine months after he landed he began to pass blood at the end of micturition. He had no pain and no frequency, and, beyond the presence of blood in his urine, suffered no inconvenience. He was three years in South Africa. His symptoms have continued without change to the present date. He was cystoscoped on January 25th, 1907, when the following appearances were found: On the posterior wall, some distance behind the trigone, the mucous membrane was raised, rough, and of a dark red colour. Scattered over its surface were small, raised, whitish bodies, round in shape, varying in size from that of a small pin's head to that of a hemp seed. The red patches were irregular in shape and size, and extended principally towards the right. Small patches destitute of white bodies were seen in the vicinity. Between and beyond these patches, healthy pale mucous membrane was seen. The trigone and ureters were normal. The urine contained numerous ova of bilharzia hæmatobia.

I need only mention Case 72, seen with Dr. Colville. A lady, æt. about 50, had had three attacks of hæmaturia, the first thirteen years ago, the second a year and a half ago, and the third a day or two before I saw her. Unfortunately, she had just cleared up the day before she was cystoscoped. There was evidence, however, on the posterior wall of the bladder of a small vessel having recently been the seat of hæmorrhage. The urine from both ureters was free from albumin and casts.

In Case 43, the hæmorrhage also ceased the day before I had the opportunity of using the cystoscope. A young medical man had pain in the right kidney, and also sometimes in the left, with frequent attacks of hæmaturia. He was sent to me by Sir Wm. Whitla to decide definitely, if possible, which kidney was affected. Radiography had failed to give any definite information, and was blamed by the patient for producing an attack of hæmorrhage. Both ureters were catheterized and albumen was found in the specimen from the right, while normal urine was obtained from the left. On August 21st, 1906, I removed from the pelvis of the right kidney a rough oxalate of lime calculus. The patient has remained quite well ever since.

In Case 12, a male, æt. 30, who slipped while carrying a sack of coals on his back and strained his side: blood clot was seen distending the orifice and adjacent portion of the ureter of the right side. He had had hæmaturia, but this had ceased a few days before I saw him. I have referred very briefly to these cases of hæmaturia, but what I have stated will serve to show the use of the cystoscope in this condition.

II. *Pyuria.*—Under this heading let me very briefly direct your attention to one or two cases in which the cystoscope was of incalulable value. Case 102, a young lady, seen with Dr. McQuitty, complained of feeling out of sorts for about three months. She had lost weight and she stated that she had to make water more frequently than formerly. Dr. McQuitty found pus and tubercle bacilli in the urine. He leaned to the diagnosis of tuberculous bladder. On introducing the cystoscope, the ureteral orifice on the right side was seen to be dilated, and the surrounding area congested. Pus was obtained by the ureteral catheter from that side, and normal urine from the left. The bladder was normal. Neither kidney was palpable, and no pain was complained of on either side. There can be little doubt but that the right kidney is tuberculous. She is receiving tuberculin injections from Dr. Houston prior to operation. Case 106, seen with Professor Sinclair, a lady, æt. about 50, had two enlarged kidneys and pus in the urine. Professor Sinclair had designs on the right on account of a nodular feeling at the lower pole. The ureteral catheter, however, showed that the left was the offender, a urine of good specific gravity and free from albumen or pus being obtained from the right. In Case 1, under the care of Drs. Darling, McKisack, and Campbell, both kidneys were palpable, the right being the larger and more painful. Pus had been present in the urine for about two years. Tubercle bacilli were present. The patient wished to have the affected kidney removed, but before doing so it was deemed advisable to ascertain the efficiency of the presumably healthy one. The right ureter pumped urine containing pus into the bladder. The left ureter was catheterized and clear urine obtained. This, however, contained a trace of albumen and was deficient as regards its molecular concentration. Dr. Houston found that the co-efficient of excretion was 1.17 instead of 2. No operation was performed. I do not think I need take up any more of your time in dealing with this group. Let me refer you to the synopsis in your hands for further cases.

III. *Frequency of Micturition.*—Frequency may be the only symptom complained of, but, as a rule, others are added as the case proceeds. The following patients sought advice chiefly because of the inconvenience of having to pass water at short intervals. Case 3, female, æt. 27, was seen with Dr. John Campbell and Dr. Hicks at the Samaritan Hospital. Her chief complaint was frequency, but she also had some bladder pain. The symptoms had been present for four years. With the cystoscope, the following appearances were found: On the posterior wall of the bladder, behind the inter-ureteric bar, there were a score or more of round, smooth golden-yellow bodies, mostly about the size of a pin's head, and clustered rather closely together. Dr. Campbell had examined the patient some days previously by Kelly's method and had found these bodies, which he says were then white in colour. Possibly the yellowish tinge was given to them by the iodoform emulsion then injected. The little bodies in question were very like the tubercles one sees on the peritoneum. The occurrence of tubercle of the bladder in this form is rare, if, indeed, it was tubercle. Probably time will enable us to confirm or correct our diagnosis. She was examined on April 2nd, 1906. A note from Dr. Currie, of Ballymena, on February 13th, 1907, to Dr. Campbell, states that the patient is as bad as ever.

Case 62, a male, æt. 57, was referred to me by Dr. Calwell, of the Royal Victoria Hospital, to whom he was sent in the first instance. He had had stricture of the urethra which had been divided on two occasions. He had had hæmorrhage from his bladder on three occasions, but for the past two years he had been free from hæmaturia. He complained now of frequency of micturition without pain, being obliged to pass water every half-hour day and night. His urine was foul-smelling, alkaline, and contained albumen, pus, and a little blood. To wash him out I had to use a metal catheter, the usual rubber one being caught at the stricture. This caused considerable hæmorrhage, evidently from the bladder wall, which was with difficulty controlled by adrenalin. The cystoscope showed the following appearances. On the superior wall, a little to the left of the middle line, there was a star-shaped oblong patch which was darker than the surrounding area. The edges of this dark patch were thick-looking and its surface depressed. There was general cystitis, as well, and the bladder would only hold about 3 ozs. A few days later I performed a supra-pubic cystotomy, and found a large irregular patch in the superior wall, the surface of which was dark, rough, and raw, with, in some places, greyish shreds attached. The edges were irregular, raised, and a little hard. The wall of the bladder at the affected spot was thicker and firmer than the smooth, pliable, comparatively healthy portion elsewhere. The patch was scraped, and the bladder drained and washed out with weak solutions of nitrate of silver. This stricture, which had begun to contract, was dilated at the same time. When examined a month later, the surface previously described was dull and lustreless, but apparently healed. Both ureters, now seen clearly, were round and open like pits in the bladder wall. He could now hold his water for 2½ hours.

Frequency may be the principal or only symptom in cases of enlarged prostate. Examination *per rectum* is not always conclusive, as in Case 16, a man, æt. 65, from whose bladder I removed two stones by litholapaxy in May, 1906. He continued to form stones, and on examining his prostate closely a projection was found which evidently prevented him from properly emptying the bladder. I removed the prostate on February 13th, 1907, and found a polypoid projection growing from the left lobe. The gland itself weighed only 4 drachms, and had embedded in its substance one large and many small stones. He is now convalescent. On examining a bladder in a patient with enlarged prostate and bringing the beak towards the meatus, large mountainous masses may be seen of a dark colour, contrasting markedly with the pale mucous membrane of the bladder in the distance. The mucous membrane over these projections is frequently congested and ecchymosed. The prostate may project so much that it is impossible to see behind it, and stones may in this way escape notice.

In Case 104, a gentleman, æt. 68, sent by Dr. Wilson, of Castleblaney, and who had no residual urine but frequency of micturition and inability to hold it for an instant after the desire to urinate came on, I found a number of round projections encircling the neck of the bladder like a collar. These evidently prevented the sphincter from acting, and caused incontinence rather than retention. The bladder held with difficulty about 4 ozs. of fluid. I could multiply cases of typical enlarged prostate, but this would serve no useful purpose as the condition is recognised most frequently without the cystoscope. I might just briefly mention that the cystoscopic examination of a bladder some months after prostatectomy does not show, as might be expected, a huge pouch or scar. It would be exceedingly difficult to say from the cystoscopic appearances that anything abnormal was present in the disposition of the parts at the neck of the bladder. The ureters are frequently found dilated, and the muscular wall hypertrophied, but beyond a little pleating of the mucous membrane at the neck, nothing abnormal is seen. This accords with the actual state of affairs as found in Case 62, a patient of Dr. Huston, of Tynan, who developed a month after his discharge a small supra-pubic sinus. When scraping this sinus, I enlarged it, and explored with my finger the interior of the bladder, and found a well-formed internal urethral opening, and a scar, felt by the finger but possibly not visible, just at the anterior end of the trigone. It would have been difficult to say that any operation had been done. I have examined cystoscopically several cases at various intervals after prostatectomy, and have found in all the same condition of affairs.

IV.—I will now refer briefly to the cases illustrating the last division of my subject, namely, those who complain of pain and frequency of micturition with pus, and, perhaps, blood, in the urine. The pain is generally referred to the glans penis, but may be in the perineum or supra-pubic region. It is occasionally felt in more distant parts. Patients presenting these symptoms are often sent to be examined for stone. Let me describe the cystoscopic findings in a few. Case 66, a male, æt. 26, was sent by Dr. Reid, of Whiteabbey. He began to suffer from frequency a few weeks before. Micturition was obligatory every hour during the day and three or four times at night. He had pain at the point of the penis, most acute just after the act. There was a little blood at the end of micturition. The cystoscope showed well-marked general cystitis. The bladder-wall was thick and congested. Both ureteric orifices could be seen in their inflamed surroundings. No stone was present. The urine was alkaline, and contained phosphates, blood and pus. With urotropin, sandal oil, and irrigations of boric acid lotion, recovery was complete in a week. Case 24, a male, æt. 38, was sent to me by Dr. McQuitty to be examined for stone. He complained of severe pain at the point of the penis, frequency of micturition every half hour day and night, and hæmaturia on pressing to get rid of his urine. I asked him to allow me to cystoscope him, but he refused when he caught sight of the apparatus. I sounded him with a negative result. Some time later he returned requesting a cystoscopic examination, as his symptoms were such that life was unbearable. On June 1st, 1906, I passed a catheter, and obtained about a pint of residual urine. After washing out the cystoscope revealed a pinkish red tumour about the size of a hazel nut hanging from the anterior wall of the bladder, so as to lie almost exactly over the internal orifice of the urethra. The tumour was composed of a bunch of leaves shaped like those of a lettuce, almost transparent, waving in the fluid. Minute vessels ran along these to the end. The edges of some of these leaf-like structures were ecchymosed. There was also some cystitis present. I removed the little tumour, which had a long pedicle, with the portion of the mucous membrane to which it was attached, by a transverse suprapubic cystotomy early in July, 1906. The patient is now quite well, holds his water all night, passes it about every six hours during the day, and is a firm believer in cystoscopy.

Case 48, an old man, æt. 80, was sent to me by Dr. Morrow, with the following history: For the past two months he had complained of pain at the bottom of his stomach, that is to say, the suprapubic region, and had passed dark, blood-stained urine. During the last fortnight before examination, he had had pain at the point of the penis, which began with micturition and ceased when the act was completed. He had frequency, passing water every half-hour, day and night. On examination, the prostrate was found not to be enlarged, and there was no residual urine. On August 10th, 1906, I cystoscoped the bladder which would only hold, with great difficulty, 4 ozs. of fluid. Bleeding was profuse and was arrested by adrenalin. On the right side of his bladder, rather towards the superior wall, one could see a broadly pedunculated tumour. The basal portion was similar in colour to that of the wall of the bladder in the vicinity, but the free, rather bulbous part was sloughy, the sloughs being dark and grey or white in colour, and floating freely in the fluid. The whole swelling pulsated with the heart beats, and was apparently about the size of a marble. The growth was probably what Mr. Hurry Fenwick calls a bald epithelioma. The duration of life in these cases averages about 2½ years (Fenwick).

Case 20 is a typical case of stone in a male, æt. 28. He had been suffering for the past eleven months from frequency of micturition day and night, with some difficulty in passing water. He had blood and pus in his urine, and suffered pain before and after micturition, especially the latter. The pain was felt at the point of the penis and in the perineum. With the cystoscope a large round, roughish, grey stone was seen lying free at the base of the bladder. General cystitis was present with patches of ecchymosis in places. On May 18th, 1906, I removed by crushing a stone weighing 2 drs. and 10 grs. when dry, consisting of a central core of urates with a phosphatic crust. The cystoscope was used during the operation to ascertain that no particle of *debris* had been left behind. The use of adrenalin during the operation allows the bladder wall to be seen at any stage of the proceedings, and limits the damage caused by the lithotrite. His bladder was re-examined ten days later by the cystoscope, and found to be free from *debris*. He is now in excellent health. The following case is introduced here to show that stone may be present without any of the usual symptoms.

Case 56, a male, æt. 50, was sent to me by Dr. McQuitty with the following history: He had had three attacks of left-sided renal colic. Four years ago he began to have uneasiness in his perineum on walking, and after micturition. He had no frequency, no pain at the point of the penis, and his urine contained neither blood nor pus. The cystoscope, however, showed a round whitish stone about the size of a marble lying free in the bladder. This I removed by crushing on October 5th, 1906. It weighed 95 grains, and consisted mainly of oxalates with about a third part of phosphates. His bladder was re-examined by the cystoscope nine days later and found free from stone or *debris*. He also continues in excellent health.

Case 67, which I saw with Dr. Hicks and Dr. John Campbell, is worthy of more than a passing notice. A young lady, previously healthy, consulted Dr. Hicks a fortnight before, stating that she had experienced some bearing-down pains the day previous. She did not at that time complain of any symptoms referable to the bladder or kidneys. Dr. Hicks examined her *per rectum*, and found a nodule the size of a pigeon's egg in the right broad ligament close to the cervix uteri. She was admitted to hospital on the same day and examined under chloroform. The same tumour was felt *per vaginam*. Her urine was clear amber, acid, and contained neither albumen nor sugar. After four days in hospital she began to complain of excessive pain in the lower abdomen with great frequency of micturition and blood in the urine. No catheter had been used—nor had the bladder been interfered with in any way. The frequency and pain became so intolerable that three or four grains of opium were required to give relief. Day and night the patient passed water every ten minutes with the greatest agony. Dr. Hicks thought that the lump referred to might be a stone in the ureter. Under chloroform, on November 13th, 1906, the bladder was washed out with adrenalin and water for nearly a hour before we could obtain a medium sufficiently clear to see anything. Even under the anæsthetic, only 3 ozs. at the most could be injected into the bladder. The cystoscope showed the ureters and neighbouring parts to be somewhat injected but not ulcerated. A small ureteral catheter was introduced into the right ureter and passed well beyond the supposed stone, which was felt *per vaginam* to be well in front of the catheter. It is more likely that the nodule found was a small fibroid. On examining the bladder further, an extensive surface covered with what looked like a diphtheritic membrane was seen on the left posterior superior wall. This could be best seen with the beak of the instrument pointing up and to the left side, and appeared to me to extend over about a quarter of the bladder-wall. It could be indented with the ureteral catheter, and was not incrusted. The urethra was now dilated and the bladder examined by Kelly's method after drying out the interior. The area now looked dark, probably on account of the removal of a layer of mucus which covered it like a film of gauze. Scattered over the surface of this large patch were dark, smooth, round nodules almost like small sloes in appearance. From the cystoscopic appearance, I ventured on the diagnosis of acute phlegmonous cystitis with sloughing of a portion of the mucous membrane, but this conclusion was not accepted by my friends who favoured that of malignant disease. Her temperature ranged from 99° to 101°. The urine now contained pus and blood. The patient was treated by Dr. Hicks by washing out the bladder with weak chinosol solutions, and for some time by drainage with a Skene-Goodman's catheter, and at the end of a month I again cystoscoped her. This time no anæsthetic was necessary, either local or general. Three ounces of fluid were left in the bladder, but more could have been tolerated. The main portion of the wall had now almost recovered its normal colour. A few hæmorrhagic spots were still present in the more healthy parts. In the left posterior superior area there was a raw surface with a beautiful rich red streaked colour which began just to the left of the middle line. The margins of this ulcer were irregular, and extended almost to the inter-ureteric bar below, and on the left side. Far to the left healthy bladder wall was seen. The ulcer now appeared to occupy about one-sixth of the wall. Both ureters looked normal. The urine was neutral, specific gravity 1020, and contained a trace of albumen, a few pus cells, bladder epithelium, and phosphates. My reading of this interesting case is that an acute cystitis occurred, and that a portion of the mucous membrane sloughed, leaving the muscular layer bare. She subsequently had white leg on the left side. I hear from Dr. Hicks that she is now almost well, and that she can retain her urine for six hours at a time.

I had hoped to say a few words in this connection upon some cases of tuberculous bladder, an affection which is unfortunately fairly common in this part of the country, but I have already used up all the time I can reasonably expect to occupy, so that I must defer to a future occasion any remarks I may have to make on this subject. I had hoped also to give a short account of the comparatively large number of cases in which I have catheterized the ureters, male and female, but this must also be postponed. I now apologize for the length of this paper and for the fragmentary character of the notes of the cases which I have had the honour to bring before your notice. My object was to satisfy you of the utility of the urethroscope and cystoscope, especially in diagnosis and I leave it to you to say if I have succeeded in so doing.

IODISED CATGUT.

By PEYTON T. B. BEALE, F.R.C.S.,
Surgeon, Great Northern Central Hospital, and
J. CLARK,
Senior House Surgeon.

Some months ago my friend Professor Hewlett drew my attention to a report of a paper read before the Medical Society of the Missouri Valley on September 8, 1906, by H. H. Everett, M.D., dealing with iodised catgut, and published in the *Medical Herald.*

It seemed to me that this was an ideal method of preparation, as it was so extremely simple and so easily carried out. I determined to try it in order to see if it would stand the severe test of use in all kinds of surgical cases.

The following account has been written by the Senior House Surgeon, Mr. Clark, who has had charge of my beds for the last six months, and I can verify every word.

I think it is important that so easy and efficient a method of preparing catgut should be generally known, and as described below it is practically the same as that published by Dr. Everett.

The great drawback to the existing methods of preparing catgut for surgical work is that those processes which efficiently sterilise it at the same time impair very markedly its tensile strength. The following method leaves the catgut as strong as, or stronger than, it was before the preparation was commenced. It has also been proved to be perfectly efficient as regards rendering the catgut sterile. It can be used either for plain catgut, or for the chromicised variety.

The raw catgut, after its strength has been carefully tested, is rubbed over with a swab soaked in methylated ether to remove any fat or other impurity which may be adherent to its surface. It is then wound on a microscope slide, only one layer being put upon each slide, and immersed in a one per cent. solution of iodine in methyl alcohol. In this solution it should be left from one to three days, according to the thickness of the strands, after which it is quite sterile, as has been proved by repeated cultivation on ordinary media. Since the strength of the catgut is not impaired by a more prolonged immersion in the iodine solution, it is convenient to leave it for a week, and then, even if a variety of sizes have been prepared together, all will be quite sterile. The catgut is removed from the solution and each slide wrapped in two layers of sterilised filter paper, a process which can be carried out with forceps, so that the fingers need not touch the catgut. A final covering of thick parchment paper is wrapped round the filter paper, and the whole stored in a dry place. When required for use the paper wrappings are removed by forceps and the catgut dropped into lotion. If plain catgut is being used, it is better to place it in methylated spirit or some spirit lotion, as a watery lotion causes swelling of the strands and makes them weaker.

Catgut prepared in this way has now been used by Mr. Peyton T. B. Beale, F.R.C.S., in all operations for a period of six months, and the results have been perfect. During this time practically all the surgical operations in vogue at the present day have been performed, and this catgut used throughout, even the skin being sutured with it, and in no case has there been the slightest irritation around the stitches or any of those troubles which we associate with imperfectly sterilised ligatures or suture materials.

Chromicised gut prepared in this way will remain firm and unabsorbed for at least 18 days, the plain gut for at least 6 days.

OPERATING THEATRES.

ST. THOMAS'S HOSPITAL.

Carcinoma of Testis.—Mr. Edred Corner operated on a man, æt. 36, who was a whitesmith, suffering from swollen testicle, which he had first noticed ten months ago, his attention being attracted to it by its size and weight, but not by pain. Latterly he had had some pain, but not of a severe nature. He was rather uncertain as to whether he had injured the part or not. The pain came on in attacks lasting for a week at a time. The swelling had been mistaken for a hydrocele, as it fluctuated freely. Under this impression it had been tapped, when it bled freely. In this connection Mr. Corner said he would like to draw attention to the different results obtained in tapping a growth or a gumma of the testicle; the former usually bleeds freely, the latter does not. In this particular case the free hæmorrhage clinched the diagnosis of neoplasm of the testicle. At present there was a large cystic swelling on the left side of the scrotum; the skin over it was very tense, and the gland was indistinguishable. As the diagnosis was undoubted, the operation of castration, Mr. Corner said, would be done through an incision in the inguinal region rather than through an incision in the scrotum; the inguinal incision was to be preferred because it can be kept aseptic. The inguinal canal was opened, the spermatic cord separated and divided as high up as possible. Mr. Corner pointed out that he did not think it worth while to attempt to remove any of the constituent structures of the cord above the internal abdominal ring. The tumour was then drawn into the wound by invaginating the scrotum, it was then freed from the skin and removed. Mr. Corner drew attention to the fact that malignant neoplasms of the testicle possessed a bad prognosis because the infection proceeded straight from the gland to the intra-abdominal lymphatics; the glands in the inguinal region were only infected when the growth had involved the skin. In the latter case the infection travelled by the superficial lymphatics, and in the former it took place through the deep lymphatics which accompany the spermatic cord. In the history of cases of carcinoma of the testicle it was, he said, extremely common to obtain a history of an injury of the gland. This patient had no such accident. Further, it was stated that pain was a constant and early symptom of malignant disease of the testicle. In this case pain was a late symptom, and then only came on from time to time, the duration of each attack being about a week, whilst in the intervals the patient had no discomfort except for the weight of the gland. There was still one further point, Mr. Corner remarked. When the man was examined, he showed complete absence of testicular sensation, a sign which, he said, the text-books inform us, was restricted to gummatious disease of the testicle; but he thought it mattered not whether the disease which has affected the testicle was growth or syphilis; so long as the testicle has been destroyed testicular sensation will be absent.

SPECIAL REPORTS.

GENERAL MEDICAL COUNCIL.

Eighty-Fifth Session.

FIRST DAY.—Tuesday, May 28th, 1907.

Dr. MacALISTER, President, in the Chair.

The official notification of the election of the following members was read:—

(a) As direct representatives for England for five years:—From December 12th, 1906: Dr. Henry Langley Browne. From January 1st, 1907: Dr. Leonard Strong McManus, Dr. Henry Arthur Latimer.

Dr. Langley Browne was introduced by Dr. Saundby; Dr. McManus and Dr. Latimer were introduced by Sir John Williams.

(b) As direct representative for Scotland for five years, from January 1st, 1907: Dr. Norman Purvis Walker. Dr. Walker was introduced by Mr. Hodsdon.

The President delivered the following:—

PRESIDENTIAL ADDRESS.

"Gentlemen,—During the recess a general election has taken place in England and Scotland, with the result that four new members have been returned to the Council in the places of Sir Victor Horsley, Mr. George Brown, Mr. Jackson and Dr. Bruce. Sir Victor Horsley retired before the beginning of our last session, in order to spare the English constituency the trouble of a bye-election. . . . After a few graceful words concerning the retiring members, Dr. MacAlister said with reference to the new members that to them we look with confidence for that willing co-operation in the fulfilment of our responsible tasks which was rendered by their predecessors. We are well assured, by their past record, that they will in addition contribute to our deliberations something that is fresh and individual. . . . As you are probably aware, I have been unexpectedly called by His Majesty to be the resident head of the University of Glasgow. The authorities of the University of Cambridge, to whom I owe my seat in the Council, and accordingly in this chair, have kindly expressed a desire that I should complete the term of five years for which I was last re-elected by the Senate. As the Senate is not limited in its choice to persons in continuous residence at Cambridge, and as I shall maintain a close connection with that University, I have agreed to retain my membership of the Council as its representative. I have made such arrangements for the conduct of office business during the interval of our sessions as will ensure that the commonwealth shall take no detriment on account of my greater distance from London. It may even be that some advantage will accrue from the opportunity afforded to your President of studying at first hand the position of medical education and practice in Scotland as well as in England.

The Lord President of the Privy Council has just furnished us with an illustration. The University of Edinburgh has framed an Ordinance making certain changes in the course of study and examinations for medical degrees. On this Ordinance two of the three other Scottish Universities have offered to the Privy Council, as they are entitled by law to do, various criticisms, of which some refer to inter-university relations rather than to general principles, others perhaps to matters of substance. In regard to such general principles and matters of substance the Lord President invites an expression of opinion on the part of the Medical Council. The Executive Committee have resolved to refer the Ordinance to the Education Committee and the Examination Committee, with the request that they will respectively report to the Council whether the provisions of the Ordinance are in conformity with its existing *resolutions and recommendations* on the subjects of professional education and professional examination.

It is with special satisfaction that I record the completion of the negotiations for medical reciprocity with the Province of Nova Scotia, to which, as you will remember, His Majesty in Council was pleased last year to apply Part II. of the Medical Act, 1886. . . . The admission of Nova-Scotian qualifications to the British Register has already, as I understand, had the incidental consequence that Canadian medical graduates, who have fulfilled the conditions applicable to the Maritime Province, are now declared to be eligible for commissions in the Royal Army Medical Corps. The Australian States, which long ago entered into reciprocal relations with this country, are already in a position to offer similar advantages to their medical graduates. It is to be regretted that graduates of Provincial Universities in Canada, other than those of Nova Scotia, are still ineligible for appointment in the Medical Services of the Crown. It now rests with the Canadian Provinces themselves to remove the disability. The Council, which has always taken a broad view of its responsibilities to the Empire in general, will doubtless give the most favourable consideration to any overtures the Provincial Governments may make to this end.

His Majesty has not yet been pleased to apply the Act to the Province of Quebec, as it is first necessary that the Privy Council should be more fully informed of the actual provisions of the local law affecting the admission to the Provincial Register of practitioners registered in the United Kingdom. We are told that the requisite inquiries are being made through the proper channels. Until His Majesty in Council is satisfied regarding the provisions in question, the

Executive Committee is unable to take further steps towards the recognition of Quebec degrees.

The Foreign Office has forwarded to the Council copies of the International Agreement respecting the Unification of the Pharmacopœial Formulas for Potent Drugs, which was signed at Brussels on November 29th, 1906, by the diplomatic representatives of eighteen States on behalf of the respective Contracting Governments. This Agreement embodies, with slight amendments, the resolutions of the Brussels Conference of 1902. It includes the following reservation which, as Chairman of the Pharmacopœia Committee I venture to suggest should be made on behalf of this country: "The Government of His Britannic Majesty declares that it reserves the right of introducing into the stipulations of the present Agreement such modifications in detail as the progress of medical and pharmaceutical science may render necessary from time to time." In drawing up the next *Pharmacopœia* it will accordingly be incumbent on the Council, in the paramount interest of international uniformity and of public safety, to make certain changes in the formulas for a few poisonous drugs and preparations. . . .

Two Bills, proposing amendments in the law relating to the practise of medicine and of dental surgery by joint stock companies, which have already received the appproval of the Council, have been introduced in the Upper House by Lord Hylton, and have passed the second reading without opposition. They were supported in principle by Lord Halsbury, late Lord Chancellor, and by the Lord President of the Council on behalf of the Government. By consent they have been referred to a Select Committee, which will shortly sit to receive evidence from this Council, and from other bodies interested, respecting the abuses against which the Bills are directed, and the sufficiency of the proposals therein contained for the purpose contemplated. The Registrar and your Legal Advisers are actively engaged in preparing for submission to the Select Committee a statement of the evidence in the possession of your Companies-Bills Committee.

A Bill to empower the Society of Apothecaries of London to confer on those who have passed its qualifying examination the title of "Licentiate in Medicine and Surgery" has passed through several of its stages in Parliament. Certain amendments in its terms, suggested by the Executive Committee in the interest of the Council, have been readily adopted by the promoters.

A question seriously affecting the position of members of the Council as a judicial body has been raised by a communication from the Chairman of the Central Ethical Committee of the British Medical Association. The communication informs us that the Annual Representative Meeting has decided that the Association should act as complainant in cases which might require to be brought before the Medical Council; and that the Central Ethical Committee is the body whose duty it would be to consider whether a given case should be so brought, and to prepare the case for our consideration.

As many members of the Council (and of the Penal Cases Committee) are members of the British Medical Association, it appeared desirable that their position in regard to complaints made by the Association, if such were brought for inquiry before the Council (or the Committee), should be made clear. I accordingly consulted our Legal Advisers, who are familiar with the *dicta* of the Lords Justices in cases (such as Leeson's and Allinson's) where the suspicion of bias or prejudice on the part of members of the Council has been alleged as a ground of appeal against its decisions. The advice is that the proper course to be taken by a member of the Council, who belongs to the Association, is not merely to withdraw from the decision of a case in which the Association acts as complainant, but to withdraw from membership of the Association altogether.

The question of acting on this advice became urgent in my own case, when, at the beginning of this month, the Registrar reported that a formal complaint against a practitioner had been lodged at the office by a branch of the Association, and that the documents awaited my consideration in pursuance of the Standing Orders. As your President, I could not take even the first step towards a judicial inquiry so long as I remained a member of the British Medical Association. I therefore, without delay, sent in my resignation to the general secretary. So soon as my resignation takes effect I shall be able to look at the complaint; but I shall not be able to take the advice of the Penal Cases Committee upon the matter until the other members have also ceased to be connected with the Association. . . ,

The Secretary for Scotland has been pleased to give directions, similar to those already given in England and Ireland, which will result in the notification to the Council of all cases in which registered practitioners are convicted in Scotland of crimes or offences punishable by fines. The thanks of the Council are due to the Government authorities for this aid to the performance of its disciplinary function. . . .

Certain decisions given recently in the Chancery Division of the High Court, in connection with our judgment in an inquiry held by the Council last year, have raised legal questions of interest regarding the scope and meaning of the statutory phrase "infamous or disgraceful conduct in a professional respect." The Chancery decisions do not in form impugn the judgment of the Council, or call in question its jurisdiction; but some of the points involved concern us so closely that I have asked the Council's Solicitor to prepare a memorandum on the subject for our information. As we are advised that an appeal against the judgments is in progress, and as the cases are therefore *sub judice* I propose that the memorandum should be communicated to the Council *in camera*. . . .

In accordance with the resolution of November 30th, 1906, I communicated to Sir Henry Howse and Mr. Alexis Thomson your acknowledgements of the valuable services they had rendered to the Council during their long tenure of office as Assistant Examiners in Surgery at the Apothecaries' Hall, Dublin, and your desire to establish a system of rotation in the appointment of such Examiners in future. From both have come letters expressing appreciation of the Council's consideration, and concurring in the suggestion that rotation is desirable. Proposals will be made to you for the appointment of two Dublin Surgeons, one to act for two years and one for four, as Assistant Examiners (and on occasion Inspectors) for the Apothecaries' Hall. Their function is an important one, for through them the Council has to perform its statutory duty of maintaining the present standard of efficiency, and that not in surgery alone, at the examinations of this Licensing Body.

In conclusion, I have to congratulate the Council on finishing another financial year with a surplus instead of a deficit. But for the heavy expenses connected with the general election, expenses which are considerably increased by the introduction of the ballot system, the surplus would have amounted to £910, or a little more than last year. Of this sum, however, £870 was expended over the election, leaving a net balance of only £40. The actual expenditure on the enlargement of our chamber, and the improvement of our property, has for the time been met by means of the surplus in hand from last year. . . .

Moved by Dr. Norman Moore, seconded by Mr. Morris, and carried by acclamation:—

"That the President be thanked for his Address, and requested to let it be printed in the Minutes."

On motion from the Chair it was agreed:—"That the following constitute the Business Committee: Dr. Norman Moore, chairman, The President, Sir Christopher Nixon, Mr. Young."

Moved by Dr. McVail, seconded by Dr. Norman Moore, and agreed to:—"That nine yearly tables be received and entered in the Minutes: The tables showed results of Professional Medical Examinations during 1906; results of Professional Dental Examinations during 1906; and results of Competition for Commissions in the Medical Staff of the Royal Navy."

Moved by Dr. McVail, seconded by Mr. Young, and agreed to:—"That the thanks of the Council be conveyed to the Director-General of the Medical Department of the Royal Navy, the Director-General of the Army Medical Service, and the Under-Secretary of State for India, respectively, for the returns which they have again furnished to the Council, with the request that these returns may in the future continue to be furnished to the General Medical Council."

Moved by Sir John Moore, seconded by Dr. Little:—"That the Governor and Court of the Apothecaries' Hall, Dublin, be requested to furnish, for the information of the Council, a statement in reference to the Final or Qualifying Examination of that Body." The motion was lost—13 against, 10 for, 9 did not vote, 2 absent.

Moved by Dr. Adye-Curran, seconded by Sir Christopher Nixon, and agreed to:—"That Sir Lambert Ormsby, late President R.C.S. Ireland, and Mr. F. Conway Dwyer, Fellow and Examiner in Surgery, R.C.S. Ireland, be appointed Assistant Examiners in Surgery to the Apothecaries' Hall, Dublin, the former for a period of two years and the latter for a period of four years, *vice* Sir Henry Howse and Mr. Alexis Thomson, retired."

The President undertook to inform the Assistant Examiners as to their statutory duties under the Medical Act, 1886.

Moved by Sir Hugh Beevor, seconded by Mr. Morris and agreed to:—"That Mr. Henry Percy Dean, L.S.A., M.B., M.S. Univ. Lond., F.R.C.S. Eng., be appointed Assistant Examiner in Surgery to the Apothecaries' Society of London for a period of four years, *vice* Mr. Peyton Beale, who retires by rotation."

REGISTRATION OF COLONIAL DEGREES.

The following report by the Executive Committee was read:—The Executive Committee report that Part II. of the Medical Act (1886) having been extended by an Order in Council to Nova Scotia (see Minutes, Vol. XLIII., pp. 195–196), they have considered the conditions under which Medical Qualifications granted in the Province of Nova Scotia shall be recognised for registration in the *Colonial List* of the *Medical Register* of the United Kingdom, and on February 27th, 1907, adopted the following resolution:—

"That any person who holds—

(1) The Diploma or Licence in Medicine, Surgery, and Midwifery granted after examination by the Provincial Medical Board of Nova Scotia, together with the Licence to practise in that Province; or

(2) The Degrees of Doctor of Medicine and Master of Surgery of the Dalhousie University, together with the aforesaid Licence to practise or

(3) The Degrees of Doctor of Medicine and Master of Surgery of the Halifax Medical College, together with the aforesaid Licence to practise,

shall be entitled to be registered in the *Colonial List* of the *Medical Register*, provided he satisfies the Registrar of the General Medical Council regarding the other particulars set forth in Part II. of the Medical Act, 1886."

DONALD MACALISTER, *Chairman.*

February 27th, 1907.

On motion from the Chair, it was agreed unanimously:—"That this report of the Executive Committee be received and entered in the Minutes; that the Registrar be directed to give effect to the resolutions therein contained; and that the Council record its satisfaction at the establishment of reciprocal relations with the Province of Nova Scotia."

The Council then adjourned.

SECOND DAY.—WEDNESDAY, MAY 29TH, 1907.

The minutes of the last meeting were read, and, as amended, confirmed.

The Council proceeded to the consideration of the case of George Covey, registered as of 1, Heathcote Street, Mecklenburgh Square, London, W.C., M.R.C.S.Eng., 1864, L.S.A.Lond., 1865, who had been summoned to appear before the Council on the following charge:—

"That you were on April 23rd, 1907, convicted of the following misdemeanours at the North London Sessions: namely, of obtaining money by false pretences, and of obtaining money by fraud while being an undischarged bankrupt."

ERASURES FROM THE MEDICAL REGISTER.

Mr. Covey was called, but did not answer to his notice.

The Solicitor read the notice to attend, the Certificate of Conviction, and the answers by the accused practitioner, dated respectively April 30 and May 17th, 1907.

Strangers, by direction of the Chair, withdrew in order that the Council might deliberate on the case *in camera.*

Strangers having been re-admitted, the PRESIDENT announced the decision of the Council, as follows:—

"That George Covey having been proved to have been convicted of divers misdemeanours, the Registrar has neen directed to erase his name from the *Medical Register.*"

The Council considered the case of Andrew Dunn Turner, registered as of 71, Marina, St. Leonards-on-Sea, M.B., Mast. Surg., 1882, Univ. Glasg., who had been summoned to appear before the Council on the following charge:—

"That you were on November 21st, 1906, convicted of the following misdemeanour at Lewes Assizes: namely, of unlawfully, maliciously, and scandalously writing and publishing an obscene letter at Hastings, on June 25th, 1906."

Mr. Turner attended in answer to his notice. He was not accompanied by Solicitor or counsel.

The Solicitor read the notice to attend, the Certificate of Conviction, and a report of the trial from the *Sussex Daily News* of November 23rd and 24th, 1906.

Mr. Turner's letters in reply to the Registrar's request for an explanation and his letter in reply to the Solicitor's Notice of Inquiry were read.

Strangers then, by direction of the Chair, withdrew, in order that the Council might deliberate on the case *in camera.*

Mr. Turner and strangers having been re-admitted, the PRESIDENT announced the decision of the Council as follows:—

"Mr. Andrew Dunn Turner,—I have to inform you that, it having been proved that you have been convicted of a misdemeanour, the Council has directed the Registrar to erase your name from the *Medical Register.*"

The Council considered the case of Edward John Havens, registered as of East Donyland, Colchester, M.R.C.S.Eng., 1879, L.S.A.Lond., 1879, who had been summoned to appear before the Council on the following charge:—

"That you were on November 5th, 1906, convicted of the following misdemeanour at Thorpe Petty Sessions, Thorpe-le-Soken Essex: namely, of obstructing the highway; also that you were on December 17th, 1906, convicted at the like Session of disorderly behaviour whilst drunk; and also that you were on April 8th, 1907, convicted of the following misdemeanour, at Mistley Petty Session: namely, of common assault."

Mr. Havens attended in answer to his notice, but was not represented by counsel or solicitor.

The Solicitor read the notice, the Certificates of Conviction, and a report of the first trial from the *Essex County Standard* of November 10th, 1906, which, in answer to a question, Mr. Havens admitted to be a substantially accurate account of the proceedings.

The Solicitor then read a report from the *Essex Telegraph* of the proceedings at the second conviction on December 17th, 1906. Mr. Havens admitted this also to be a substantially accurate account of the proceedings.

The Solicitor also read a report from the *Evening Standard and St. James's Gazette*, of April 8th, 1907.

A letter from Mr. Haven's solicitors, Messrs. Birkett, Ridley and Francis, of Ipswich, in reply to the Registrar's request for an explanation, and a further letter from them in answer to the Solicitor's Notice of Inquiry were read.

Mr. Havens then addressed the Council on his own behalf, and answered a question put to him from the chair, and questions put to him by the Legal Assessor and by members of the Council through the chair.

Strangers then, by direction of the Council, withdrew, in order that the Council might deliberate on the case *in camera*.

Mr. Havens and strangers having been re-admitted, the PRESIDENT announced the decision of the Council as follows:—

"Mr. Edward John Havens,—The Council have deliberated carefully on the convictions which have been proved against you, but they have adjourned the further consideration of your case till the November Session, when you should be present to hear the result of their final deliberations.

The Council proceeded to the consideration of the report of the Dental Committee on the charge against James Marston, in regard to whom the Dental Committee had found that the following facts were established by evidence.

(*a*) The said James Marston is on the *Dentists' Register* as in practice before July 22nd, 1878, and of the address: The Shrubbery, East Howe, Kinson, Bournemouth.

(*b*) The said James Marston was convicted of bigamy on January 16th, 1906, at the Dorset Assizes, and was sentenced to twelve months' imprisonment with hard labour.

Strangers having, by direction of the chair, withdrawn, the Council deliberated on the case *in camera*.

Strangers having been re-admitted, the PRESIDENT announced the judgment of the Council as follows:—

That James Marston having been proved to have been convicted of a felony, the Registrar has been directed to erase his name from the *Dentists' Register*.

The Council proceeded to the consideration of the report of the Dental Committee on the charge against Thomas William Frederick Stewart, in regard to whom the Dental Committee had found that the following facts were established by the evidence:—

That Mr. Stewart was on November 21st, 1906, convicted at Lewes Assizes of feloniously embezzling the several sums of 10s. on July 15th, £1 8s. on September 23rd, and £5 5s. on October 7th, 1906, moneys of Frederick Charles Proctor, his master.

Mr. Stewart attended in answer to his notice.

The report of the Dental Committee having been read, leave was granted to Mr. Stewart to address the Council in regard to the report.

Mr. Stewart and strangers having, by direction of the Chair, withdrawn, the Council deliberated on the case *in camera*.

Mr. Stewart and strangers having been re-admitted, the PRESIDENT announced the decision of the Council as follows:—

"Thomas William Frederick Stewart,—It having been proved that you have been convicted of a felony, the Registrar has been directed to erase your name from the *Dentists' Register*."

The Council resumed the consideration, adjourned from November 29th, 1906, of the facts proved against William Henry Moseley and James Parkinson, whose names appear on the *Dentists' Register* as "in practice before July 22nd, 1878," and who were connected with the company of Foley's Limited.

At the conclusion of the proceedings on November 29th, 1906, the President announced *seriatim* that in the cases of William Henry Moseley and James Parkinson, the further consideration of the charge against them had been postponed until the next Session of the Council, of which due notice would be given them, and at which they would be expected to be present.

In regard to these cases the Dental Committee, at its meeting on May 27th, 1907, found that the following facts were established by the evidence:—

Both Mr. Moseley and Mr. Parkinson have since the hearing of the case by the Council in November last done their best to sever their connection with the Company, and they have both parted with their shares in the Company, and they have respectively practised at Ipswich and at Uxbridge Road independently of the Company, and there is no evidence that their professional conduct in the interval has been otherwise than satisfactory.

Mr. Parkinson attended in answer to his notice. Mr. Moseley was absent owing to illness, nor was he represented by solicitor or counsel.

The Registrar having read the supplementary report, the President announced that a letter had been received from Messrs. Kerr and Ramsden, Mr. Parkinson's solicitors, stating that they had inspected the register of shareholders in Foley's, Limited, and that Mr. Parkinson's shares had been transferred, as he had stated.

This closed the public proceedings, and the PRESIDENT announced that only those who had been members of the Council at the first hearing of the case in November could take part in the deliberations.

Strangers having, by direction of the Chair, withdrawn, the Council deliberated on the case *in camera*.

Strangers having been re-admitted, the PRESIDENT announced the decision of the Council as follows:—

"That the Council having further considered the charge proved against James Parkinson and William Henry Moseley, and the reports of the Dental Committee thereon, does not judge them guilty of infamous or disgraceful conduct in a professional respect.

Strangers having again, by direction of the Chair, withdrawn, the Council proceeded to the consideration *in camera* of a report by the Executive Committee on a communication received from the British Medical Association.

Strangers having been re-admitted it was moved by Dr. Norman Moore, seconded by Sir John Moore, and agreed to:—

"That the report by the Executive Committee on a communication from the British Medical Association be received and entered in the Minutes."

In the report it was resolved:—"That the Executive Committee, being advised that no Member of the British Medical Association should act as a member of the Penal Cases Committee, or take part in adjudicating as a Member of the Council in cases in which the British Medical Association or any branch of it acts as complainants are unanimously of opinion that it is under the circumstances undesirable that a member of the Council should during his tenure of office be a Member of the British Medical Association or any other body, which may submit complaints to the Council for inquiry."

Moved by Dr. Saundby, seconded by Sir T. McCall Anderson, and agreed to:—

"That a copy of the report of the Executive Committee on the communication from the British Medical Association be sent to the General Secretary of that Body for its information."

Moved by Dr. Saundby, seconded by Sir John Moore and agreed to:—

"That the report by the Executive Committee be approved by the Council."

Strangers then, by direction of the Chair, again withdrew, in order that the Council might receive *in camera* a communciation from the solicitor in regard to certain dental cases.

Strangers having been re-admitted, it was moved by Sir John Williams, seconded by Mr. Young, and agreed to:—"That the report by the Students' Practical Midwifery Committee as to further communications sent by the Licensing Bodies and Teaching Institutions be received and entered on the Minutes."

Moved by Sir JOHN WILLIAMS, seconded by Sir CHRISTOPHER NIXON, and agreed to:—"That the report by the Students' Practical Midwifery Committee as to the inclusion of Clinical and Practical work in the Qualifying Examinations in Midwifery and Gynæcology, as read by the Chairman, be received and entered in the Minutes."

Moved by Sir John Moore seconded by Dr. Lindsay Steven, and agreed to :—" That the following report from the Public Health Committee be received, entered on the Minutes and approved " :—

The Public Health Committee report that, in accordance with the Standing Orders, they met on May 28th, 1907, and that no business came before them for consideration and report.

As the Chairmanship of the Committee had become vacant owing to the fact that Dr. Bruce's membership of the Council had ceased, the Committee selected Mr. Power as Chairman.

The Council then adjourned.

THIRD DAY.—THURSDAY, MAY 30TH, 1907.

Dr. MacAlister, President in the Chair.

The minutes of the last meeting were read, and, as amended, confirmed.

STUDENTS AND THE PRACTICE OF MIDWIFERY.

Moved by Sir John Williams seconded by Mr. Young :—

" That the following be substituted for the existing recommendations of the Council, in regard to instruction in midwifery :—' Section 1.—Every student before commencing the study of practical midwifery shall be required to have held the offices of Clinical Medical Clerk, and Surgical Dresser, and to have attended a course of lectures on Surgery and Midwifery.' "

Amendment moved by Sir John Moore, seconded by Dr. Pye-Smith :—" That after the words ' course of lectures ' and before the words ' Surgery and Midwifery' the word ' Medicine ' be inserted."

After a discussion this amendment was lost.

Further amendment moved by Sir John Moore, seconded by Sir T. McCall Anderson :—" That the words ' Surgery and ' be omitted."

This amendment was lost.

Further amendment moved by Dr. Mackay, seconded by Dr. Finlay :—" That after the word ' required ' in the original motion the following words be substituted :—' To have attended a course of Clinical instruction in Medicine, and to have held the office of Surgical Dresser, and to have attended a course of lectures on Surgery and Midwifery.' "

The amendment was lost, and the original motion was then put and carried *nem con.*

Moved by Sir John Williams, seconded by Mr. Young :—" That Section (2) of the proposed recommendations be adopted, viz :—

> " ' Every student shall be required either—
>
> " ' (*a*) To have regularly attended the indoor practice of a Lying-in Hospital, or the lying-in wards of a General Hospital, for a period of three months ; and after having received therein practical instruction in the conduct of labour, under the personal supervision of a medical officer, to have conducted twenty cases of labour under official medical supervision ; or
>
> " ' (*b*) To have conducted not less than twenty cases of labour, subject to the following conditions :—
>
> > " ' That he has, during one month, given regular daily attendance upon the indoor practice of a Lying-in Hospital or the lying-in wards of a General Hospital ; and that he has therein conducted cases of labour under the personal supervision of a Medical Officer of the Hospital, who shall, when satisfied of the Student's competence, authorise him to conduct outdoor cases under official medical supervision.' "

Amendment moved by Dr. Saundby, seconded by Mr. Morris :—" That before ' every ' in the first line the following words be inserted :—' Where the necessary Hospital facilities exist it is desirable that,' and that in the same line the word ' should ' be substituted for the word ' shall.' "

After a discussion this amendment was lost.

Further amendment moved by Dr. Langley Browne, seconded by Dr. Lindsay Steven, and agreed to :—" That in Clause (*b*) after the words ' General Hospital,' the following words be inserted, ' or of a Poor Law Infirmary having a resident Medical Officer recognised for that purpose by the Licensing Bodies.' "

Further Amendments moved by Sir Charles Ball, seconded by Sir T. McCall Anderson :—" That in (2) (*a*) the word ' ten ' be substituted for the word ' twenty.' " and " That in (2) (*b*) the word ' fifteen ' be substituted for the word ' twenty.' "

Both amendments were lost.

The original motion as amended was then put as a substantive motion, and agreed to.

Moved by Sir John Williams, seconded by Dr. Latimer, and agreed to :—" Section 3.—No certificate that the Student has conducted the above-mentioned twenty cases of labour should be accepted unless it is given by a member of the staff of a Lying-in Hospital or of the Maternity Charity of a General Hospital, or of a Dispensary having an obstetric staff recognised for that purpose by the Licensing Bodies, or of a Poor Law Infirmary having a resident Medical Officer as recognised."

Moved by Sir John Williams, seconded by Dr. Latimer, and carried (16 for, 11 against, 4 did not vote ; 3 absent) :—" That the attention of the Licensing Bodies be called to the necessity, in the public interest, of instituting Clinical and Practical Examinations in Midwifery and Gynæcology in connection with each of the Qualifying Examinations."

Moved by Sir John Williams, seconded by Dr. Lindsay Steven, and agreed to after a discussion :—" That copies of these resolutions, and of the reports of the Students' Practical Midwifery Committee be sent to the Licensing Bodies and Teaching Institutions of the United Kingdom for their information."

Moved by Dr. Mackay, seconded by Dr. Norman Moore, and agreed to :—" That the Interim Report of the Education Committee on various matters submitted to it by the General Council be received and entered on the Minutes."

Dr. Mackay made a long and very interesting speech in which he gave statistics as to the ages of entrants, the length of curriculum, &c., in England, Scotland and Ireland ; he received congratulations for the work he had done.

Moved by Dr. Mackay, seconded by Dr. Norman Moore, and agreed to :—" That the President be authorised to apply to the Licensing Bodies for information regarding the dates at which the various professional examinations were entered for and completed in the cases of those of their Licentiates the statistics of whose educational career are included in the table upon which the foregoing report is founded."

Moved by Dr. Pye-Smith, seconded by Mr. Tomes, and agreed to :—" That the report by the Finance Committee on Income and Expenditure for the year 1906 be received and entered in the minutes and adopted."

The report may be considered satisfactory as it contained a surplus, in spite of the expenses attendant on the election of Direct Representatives.

Moved by Mr. Tomes, seconded by Dr. Lindsay Steven, and agreed to :—" That the report by the Dental Education and Examination Committee, be received and entered in the Minutes."

Moved by Mr. Tomes, seconded by Mr. Morris, and agreed to :—" That the application of the University of Sydney for the recognition of its degree of Bachelor of Dental Surgery be acceded to."

Moved by Mr. Tomes, seconded by Dr. Lindsay Steven, and agreed to :—" That it be represented to the Secretary of State for the Colonies that it is desirable that recognition of foreign Dental Diplomas shall only be granted in the case of those countries which give reciprocal recognition to British Diplomas in Dental Surgery."

Moved by Dr. McVail, seconded by Mr. Young, and agreed to :—" That the report by the Examination Committee on the returns as to Examinations for the Services received by the Council on Tuesday, May 28th, 1907, be received and entered in the Minutes."

Moved by Sir HUGH BEEVOR, seconded by Dr. NORMAN MOORE, and agreed to :—" That the report by the Students' Registration Committee be received, entered in the Minutes, and approved."

Moved by Dr. NORMAN MOORE, seconded by Mr. MORRIS, and agreed to :—" That the nominations of the Branch Councils for the Examination Committee, the Education Committee, and the Public Health Committee be adopted.

On the motion of Dr. NORMAN MOORE, seconded by Mr. MORRIS, the names proposed for the Pharmacopœia Committee, the Finance Committee, the Dental Committee, the Dental Education and Examination Committee, and the Students' Registration Committee were agreed to.

The PRESIDENT announced that the following had been elected members of the Executive Committee :—Sir Hugh Beevor, Dr. Pye-Smith, Mr. Young, Mr. Tomes, Sir John Tuke, Dr. McVail, Sir John Moore, Sir Charles Ball. And that the following had been elected Members of the Penal Cases Committee :—Dr. Saundby, Mr. Tomes, Dr. Finlay, Sir Christopher Nixon.

The Council then adjourned.

FOURTH DAY.—FRIDAY, MAY 31ST, 1907.

DR. MACALISTER, President, in the Chair.

THE minutes of the last meeting were read, and, as amended, confirmed.

Moved by Dr. NORMAN MOORE, seconded by Sir JOHN MOORE, and agreed to :—" That the report by the Pharmacopœia Committee be received, entered in the minutes, and approved."

The Council proceeded to the consideration of reports by the Education Committee and the Examination Committee on the proposed Ordinance by the University Court of the University of Edinburgh to alter Ordinance No. 15 of the Commissioners under the Universities (Scotland) Act, 1889, Edinburgh No. 1.

Moved by Dr. MACKAY, seconded by Dr. NORMAN MOORE, and agreed to :—" That the following report by the Education Committee be received and entered in the Minutes."

The Education Committee report that the changes embodied in the proposed new Ordinance of the University of Edinburgh are in accordance with the requirements of the Council in regard to professional education.

JOHN YULE MACKAY,
May 29th, 1907. Chairman.

Moved by Dr. MCVAIL, and seconded by Sir JOHN MOORE, that the report by the Examination Committee be received and entered in the minutes.

The PRESIDENT called attention to the fact that the recommendation contained in the report of the Examination Committee was based on a misconception as to the bearing of No. 13 of the Council's recommendations in regard to professional examination, namely :

" 13.—Seeing that the practice of different authorities varies on the question whether a student who fails to satisfy the examiners in either one or two of the several subjects of medicine, surgery, and midwifery should be referred on all of them or only on those in which he fails, the Council recommends that some general principle should be adopted with reference to this matter ; and suggests that a percentage of not less than 60—supposing that the pass requirement be 50 per cent.—should be exempt from re-examination in such subject."

Dr. MCVAIL, seconded by Sir JOHN MOORE, substituted the following motion, which was agreed to :—" That the report of the Examination Committee down to the end of the parallel columns be received and entered in the minutes as follows :—

(B) REPORT BY THE EXAMINATION COMMITTEE.

For the information of the Medical Council the Committee puts in parallel columns the Sections of the Ordinance as at present in force and the proposed altered Sections.

First column, Present Ordinance.
Second column, Proposed New Ordinance.

I. Section XI. of Ordinance No. 16 of the said Commissioners—Edinburgh, No. 1, Regulations for Degrees in Medicine—shall be altered to read as follows :—

Each candidate shall be examined both in writing and orally, and also clinically where the nature of the subject admits, in the following divisions—viz., *First*, in Botany, Zoology, Physics, and Chemistry ; *Second*, in Anatomy and Physiology ; *Third*, in Pathology and Materia Medica and Therapeutics ; and *Fourth*, in Surgery and Clinical Surgery, Medicine and Clinical Medicine, Midwifery, Forensic Medicine and Public Health.

In subjects which admit of practical instruction the examination shall be such as to test the practical requirements of the candidate.

Provided always that if a candidate have completed in a University of the United Kingdom, or in any other University specially recognised for the purpose by the University Court, a course of study, and have passed an examination in Botany, Zoology, Physics or Chemistry, qualifying for a degree in Science or in Arts he shall be held to have passed his examinations in the said subject or subjects ; provided that in the case of a university not in the United Kingdom the course of study and the standard of examination are satisfactory in the judgment of the Senatus Academicus.

II. Section XII. of the said Ordinance, No. 16, shall be altered so as to read as follows :—

Candidates who profess themselves ready to submit to an examination in any of the subjects comprised in the first division, viz., Botany, Zoology, Physics, and Chemistry, may be admitted to examination in one, or in any number, of these subjects, at any examination held after they have attended the necessary qualifying course or courses in each of the subjects professed.

III. Section XIII. of the said Ordinance, No. 16, shall be altered so as to read as follows :—

Candidates who have passed their examinations in the subjects comprised in the first division may be admitted to examination in each of the subjects of the second division, after they have attended the necessary qualifying course or courses in that subject—viz. : in Physiology at any time ; in Anatomy at any time after the end of the first half-session of their third winter session.

IV. Section XIV. of the said Ordinance, No. 16 shall be altered so as to read as follows :—

Candidates who have passed their examinations in the subjects comprised in the first and second divisions may be admitted to examination in each of the subjects of the third division after they have attended the necessary qualifying course or courses in that subject, viz. :—in Pathology at any time after the end of the third summer session in the case of those students who begin the Medical Curriculum in October, and at the end of the fourth summer session in the case of those students who begin their medical curriculum in May ; and in Materia Medica at any time after the end of the fourth winter session ; provided always that candidates may be admitted to examination in Practical Pharmacy, and also the physical, chemical, and botanical characters of medicinal substances, at any examination held after they have attended the necessary qualifying course of instruction in that subject.

V. Section XV. of the said Ordinance, No. 16, shall be altered so as to read as follows :—

Candidates who have passed their examinations in the subjects comprised in the first, second, and third divisions may be admitted to examination in each of the subjects of the fourth or final division after they have attended the necessary qualifying course or courses in that subject—viz., in Forensic Medicine and Public Health at any time ; in Midwifery at any time after the end of the first half-session of the fifth winter session ; in Practice of Medicine and Surgery at any time after the end of the fifth winter session ; and in Clinical Medicine (including the subject of the Diseases peculiar to women) and Clinical Surgery at the end of the fifth year of study.

Moved by Dr. MACKAY, seconded by Dr. NORMAN

MOORE, and agreed to :—" That the report of the Education Committee be adopted."

Moved by Dr. MCVAIL, seconded by Sir JOHN MOORE: —" That the Medical Council is of opinion that when subjects which are usually taken together are entered for singly, the pass standard should be at least 60 per cent."

After a discussion the motion was lost—17 against, 7 for, 5 did not vote, 5 absent.

Moved by Mr. THOMSON, seconded by Dr. MACKAY, and agreed to (15 for, 3 against, 9 did not vote, 7 absent) :—" That the reply of the Council to the Lord President of the Privy Council be as follows :—

" That the Council have considered the proposed Ordinance of the University of Edinburgh, and find nothing therein which is contrary to the Council's resolutions on professional education and examination."

The PRESIDENT announced that he had received letters from Sir Lambert Ormsby and Mr. F. Conway Dwyer, accepting the position of Assistant Examiners in Surgery to the Apothecaries' Hall, Dublin, and undertaking to carry out the duties assigned to them by the Medical Act, 1886.

Moved by Dr. NORMAN MOORE, seconded by Sir JOHN BATTY TUKE, and agreed to unanimously :—

" That Mr. Allen be appointed General Registrar of the Council till the end of the Summer Session, 1908."

Moved by Dr. NORMAN MOORE, seconded by Dr. LITTLE, and agreed to unanimously :—" That the best thanks of the Council be given to the President for his able services in the chair during the present Session."

The Council then rose.

CENTRAL MIDWIVES' BOARD.

MEETING HELD MAY 30TH, 1907.

The President, Dr. CHAMPNEYS, in the Chair.

IN the beginning a letter was read by the Secretary from the Clerk of the Council, transmitting an order in Council, approving the revised rules for the period ending September 30th, 1909, after which the REPORT OF THE MIDWIVES' ACT AMENDMENT COMMITTEE was submitted, it being recommended that :—" The Board should be enlarged by the addition of one member to be nominated by the Incorporated Society of Medical Officers of Health," which brought up the often-discussed subject of lay representation.

Dr. STANLEY ATKINSON moved that, as in his opinion, the Board was not large enough for the work, six members should be added, three from municipal boards, one each from the College of Physicians and College of Surgeons, and one from the Apothecaries' Society of London.

Sir WILLIAM SINCLAIR remarked that he wished to state his own opinion not only to the Board, but to the medical Press, that the C.M.B. should be entirely constitutional, and composed of medical men. Moreover, the London Colleges of Physicians and of Surgeons were already sufficiently represented and a slight had been put on younger universities. He did not wish in any way to disparage much useful service done by the lay members, nor did he expect his opinion to influence, but he felt bound to express it. He also proposed that as he had not come from Manchester to discuss the suggested nine alterations in the Midwives' Act, that the Board should proceed to the agenda.

After a somewhat heated discussion between the lay and medical members this was agreed to, and a letter was read from the Clerk of the Council, transmitting a copy of a letter from the Medical Officer of Health for Manchester, with regard to a proposed additional rule regulating the practice of midwives.

Sir WILLIAM SINCLAIR asked why a copy of the letter was not on the agenda, and asked that copies, or the gist of letters should be put there.

Dr. PARKER YOUNG said that the answer to Manchester as framed was hardly courteous—" On the next revision of the rules." How were they to know when the Board chose to revise the Rules ? It would be better to say that intimation of revision would be sent. This was agreed to.

A letter was read from Dr. Fram Gotla, enquiring whether instruction by correspondence only entitled a teacher to sign a certificate. Answer was returned that the words " lectures " and " attended " precluded such signing.

The following gentlemen were then appointed examiners for the London Centre : R. Drummond Maxwell, M.D., F. E. Taylor, M.D., J. Abernethy, Willett, M.D.

TRAINING SCHOOLS FOR MIDWIVES.

Applications for approval as Training Schools from Bradford Union Maternity Hospital, and the Queen Victoria Nursing Institute, Wolverhampton, were read, the first being granted, the latter refused, whereupon

Sir WILLIAM SINCLAIR said he thought it strange and unreasonable to encourage Unions where the least desirable were born, and to obstruct places where a better class of births took place. He was strongly against pauper births. More places of the second class were required, especially in London.

The PRESIDENT explained that the refusal was only *pro tem*, there being neither beds nor teachers as yet for the Maternity Ward, and the Board proceeded to the discussion of minor affairs.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, June 2nd, 1907.

TREATMENT OF VOMITING.

AMONG the substances that can be employed the most frequently cocaine takes the first place, given either in pills or mixture. It may be associated with either morphia or antipyrine.

Hydrochl. of morphia, gr. ¼
Hydrochl. of cocaine, gr. ¼.
Lime water, ozs. 4.

A tablespoonful every hour, or

Hydrochl. of cocaine, gr. 1.
Antipyrine, grs. 30.
Syrup of orange, oz. 1.
Water, ozs. 4.

A dessertspoonful every hour.

Tincture of iodine is given in 5-drop doses every half hour up to 10 or 15 drops. Dr. Huchard prescribes it in the vomiting of pregnancy associated with chloroform :—

Tincture of iodine, drachm 1.
Chloroform, drachm 1.

Ten drops three times a day.

The following is an excellent formula :—

Hydrate of chloral grs. 30.
Spirit of chloroform, drachm 1.
Peppermint water, ozs. 4.

A tablespoonful every quarter of an hour.

In cancer of the stomach or round ulcer vomiting is frequent and provoked by the pain produced by the contact of food on the ulcerated membrane.

In such cases absolute rest of the organ should be prescribed ; all solids should be suppressed for a time, only a tablespoonsful of iced milk allowed at prolonged intervals, and return to solid food should be made progressively and with great prudence. The pain is relieved by large doses of bicarbonate of soda, which act in modifying the gastric secretion.

Bicarb. of soda, grs. 8.
Chalk, grs. 5.
Calcined Magnesia, grs. 5.
Belladonna powder, gr. ¼.

For one wafer, two to four a day.

Periodical vomiting, or that coming on suddenly without any particular phenomenon between times should be treated by iced or effervescing drinks ; bromides, belladonna, opium, valerian, revulsion by mustard applied to the epigastrium, hot applications, or, on the contrary, the ice bag.

As regards prophylactic treatment, a severe regimen will be prescribed, nothing liable to irritate the gastric organ should be allowed; constipation should be treated and the patient advised to employ the cold douche and take exercise.

Plantar and Palmar Hyperhydrosis.

Sweating of the hands and feet is sufficiently annoying at all times, but it becomes a regular infirmity in the warm season.

The treatment differs according to authors, but one or other of the following formula will be found useful:—

Permanganate of potash, grs. 5.
Water, quart 1,
or
Formol, drachms 4.
Friar's balsam, drachms 3.
Water, quart 1.
As local baths (warm).

If, instead of being cold and cyanosed, the feet and hands are hot, the baths should be cold, and applications will be made of:—

Icthyol, oz. 1.
Water, drachms 4.
Lanoline, oz. 1,
or
Naphthol, drachm 1.
Glycerine, drachms 3.
Proof spirit ozs. 3.
Water. oz. 1.

As lotions twice a day:

Tannin, drachm 1.
Proof spirit, ozs. 6.
Water, ozs. 3,
or
Sulphate of quinine, drachm 1.
Proof spirit, ozs. 2.
Water, 4 ozs.

Besides baths and lotions, the following powder might be employed:—

Fuller's earth, ozs. 3,
Subnit. Bismuth, oz. 1.
Salicylic acid, drachm 1.
Tartaric acid, drachm 1.

While a piece of blotting paper steeped in the following mixture may be placed in the boots:—

Permanganate of potash, grs. 15.
Thymol, grs. 6.
Water, ozs. 4.

GERMANY.

Berlin, June 2nd, 1907.

At the Deutsche Gesellschaft für Chirurgie, Hr. Ehrhardt spoke on the

True and False Diverticula of the Gall-Bladder.

as a contribution to the ætiology of pseudo-recurrences after gall-stone operations. He discussed the significance of the false diverticula with circumscribed dilatation of the wall of the gall-bladder, arising like the tissue from preformed Luschka canals as regards retention of calculi, mucus, and pus. He laid stress on the fact that calculi lying in such diverticula, as well as the diverticula themselves, could easily be overlooked in cystotomy, and that from them a recurrence could easily arise that was no recurrence, but merely a result of the operation being only imperfectly performed. If extirpation of the gall-bladder was carried out to the opening of the cyst into the bile duct, such a thing could not occur. The speaker also showed interesting preparations from which it could be seen that gall-stones might occasionally be broken up and dissolved by pancreatic tissue growing into them

Hr. Sprengel, Brunswick, spoke on

Retroperitoneal Abscesses of the Bile Passages.

He had operated on a case of abscess that had descended from the bile passages to the back of the ascending colon. No such case had hitherto been recorded in literature. An examination of the case was made post-mortem, and it was shown that a perforation of the ductus choledochus just at the junction of the cystic duct originated this trouble. Anatomically it was difficult to understand how suppuration from the bile passages lying intraperitoneally should find its way to parts lying extraperitoneally. He had tried to make fluid take this course by experiments on the cadaver, but could never succeed. He concluded, therefore, that adhesions had formed posteriorly between the bile passages and the retroperitoneal space. He thought that lumbar counter incision should always be made in such cases.

Hr. Anschütz, Breslau, gave a contribution on

Resection of the Liver.

He said that resection of the liver was now carried out at the Mikulicz (now Garré) Klinik without any special technical appliances, but with careful ligature of the vessels. The tissue when it was thin was cut through with a sharp instrument under manual compression; where the tissue was thicker, after intrahepatic ligature causing pressure. This was applied by means of a Deschamp or similar needle. Then all the vessels on the cut surface were ligatured, and the wound surfaces united by suture, for which not much approximating force could be used. The liver wound was now placed intra-peritoneally by Garré, and the abdominal wound closed, whilst Mikulicz treated it extra-peritoneally. In order to open up the liver sufficiently, the suspensory and coronary ligaments were cut through if necessary. Resection of the ribs also was advisable from the cartilage of the sixth downwards. This method of procedure was better than a transpleural one. It was to be recommended also in searching for a subphrenic abscess, and also on the left side for operations on the fundus of the stomach and about the cardiac orifice.

Hr. Riedel pointed out the danger of resection of the costal cartilages; infection might follow, and this led generally to a total destruction of it by a long and dangerous process. With regard to subserous extirpation, he pointed out that this could only be done in the case of aseptic gall-bladders, not when they were inflamed and adherent. In the latter case the essential thing was to take care of the artery and to isolate the cystic duct as far as the hepatic branch.

Hr. Bockenheimer, Berlin, spoke on

The Treatment of Tetanus,

basing his remarks on his clinical and experimental studies. He would treat all wounds prophylactically as regarded tetanus. During the Japanese war, wounds were treated with Peruvian balsam and remarkably few cases of tetanus occurred. He had discovered that fatty substances acted antagonistically as regarded tetanus, and he recommended antitoxin ointment for local treatment. He had made his investigations in the Berlin Institute for Infective Diseases under the direction of Professor Wassermann.

The *Deutsch Med. Zeitung*, No. 36, has a reference to Further Experiences in Lumbar Anæsthesia with tropacocain, novocain, and, above all, stovaine. The author, Dr. Thorbecke, Heidelberg, would have no comparisons made at present between general anæsthesia and the lumbar form, for the reason that the one has nearly reached its limits as regards perfectibility, whilst the latter is still in its infancy. Lumbar anæsthesia is indicated in cases in which it would be unsafe to use general anæsthesia, particularly in old and decrepid individuals and in diabetes. The contra-indications are septic diseases, changes in the spinal column itself, diseases of the cord and brain, and certain groups of hysteria. Lumbar anæsthesia with semi-consciousness (Dämmerschlaf) is claimed as a humane procedure. Its advantages lie in complete relaxation of muscles; in operations under it having less effect on the system at large than general narcosis; in its being permissible to give nourishment, if required, immediately this operation is over, and in the elimination of post-operative bronchitis and pneumonia. Its disadvantages lie in the accessory and after-effects; these depend on dosage and the quality of the preparation made use of, in the technique and the degree of elevation of the pelvis. At present it appears to be suitable for use in hospital only.

AUSTRIA.

Vienna, June 2nd, 1907.

HÆMOLYSIS.

MULLER gave a history of his experiments in conjunction with Landsteiner and Poetyl to the members of the Gesellschaft in order to confirm or disprove Wassermann and Plant's discovery that cerebro-spinal fluid from a paralytic mixed with syphilitic material, prevented hæmolysis in progressive paralysis, a phenomenon which they have denominated "complemental union." Müller told the members that he and his co-adjutors had come to the conclusion after careful observation that dementia paralytica lends itself more to this action of inhibited hæmolysis than any other of that class, such as dementia præcox, delirium tremens, &c. The cerebro-spinal fluid of the paralytic when used in larger doses than Wassermann used, also acts as an anti-hæmolytic. Müller found that this inhibition property, without any antiseptic, except the addition of ½ per cent. of carbolic acid, was always present, but it was destroyed by 80° centigrade—*i.e.*, 176 Fahr. The anti-hæmolytic action of Wassermann will be found a valuable diagnostic in paralytics arising from syphilis.

This inhibitory reaction can be obtained with the same intensity in the mixing of paralytic serum and syphilitic material by mixing the spinal fluid with an extract taken from "condylomata acuminata," which if treated in the same manner as the foregoing loses its effect.

The question still remains unsolved whether Wasserman and Plant's phenomenon will prove a specific for the disease, as any anti-syphilitic property could not be discovered by the experiments, but they must admit that the complemental reaction does exist.

Kraus also recorded his investigations which he had made along with Volk and Dermatology. They found that serum from normal people and serum from a syphilitic in the eruption stage when mixed with an extract taken from a primary chancre inhibit the hæmolysis; the normal serum when mixed has a similar value of 0.1 to 0.05 of inhibition. Further experiments proved that normal serum with the same value as Wassermann's acted as a specific for syphilis, which has been confirmed by Ranzi in the institute. Many sera alone are able to inhibit the hæmolysis without any addition of extracts, while others require extracts from normal organs. We may conclude then if Wassermann, Neiser and Bruck's theory of the complemental deviation be a specific for syphilis many other normal sera are quite as efficient.

PERTUSSIS AND BACILLUS.

Albrecht reported the result of his investigations of 200 cases of pneumonia following pertussis which died after varying periods. The sputa of 70 had been examined from beginning to end, and in every one the Eppendorf bacillus was present and cultivated. This bacillus was first introduced by Jochmann and Krause, which they denominated a saprophyte, but affirmed that it was more numerous in cases dying from whooping cough. Albrecht does not admit the common presence of the bacillus as in metastatic abscesses, meningitis, pericarditis, and peritonitis, the same bacillus is found in the dead body. Hitherto the Eppindorf bacillus has been confounded with the influenza, measles and pneumonia bacilli, as no morphological or biological distinction has been noted. Albrecht has injected into guinea pigs this whooping-cough bacillus, and has found the agglutinating power of high value which is obtained in one hour or 62° cent. He found this value to vary between 1 in 1400 and 1 in 600, while in the blood taken from a child suffering from pertussis it was nil. He considers it a potent organism, but in several cases of intravenous injection with bouillon he found endocarditis in the mitral valves, which he exhibited to the members, and from this morbid product he again cultivated the whooping-cough. Other fresh preparations showed yellow patches on the right side of the heart, on the liver, and acini of the kidney. The result is calcification, degeneration and necrosis of the vessels frequently met with in influenza, which may explain the alteration. Bordet a year ago, in a perfectly recent case of whooping cough, isolated the same bacteria which he believed to be the cause of the disease, but from the transitions we meet with in experiments it is difficult to decide with our present knowledge.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

CEREBRO-SPINAL MENINGITIS IN GLASGOW.—The outbreak of this disease is discussed by Dr. A. K. Chalmers, Medical Officer of Health, in a report to the Health Committee of the Town Council. There is a considerable volume of evidence that under average conditions cerebro-spinal fever is possessed of a limited range of infectivity; that it in most instances spreads through the agency of an intermediary, but that under conditions which tend to produce air impurity in confined spaces, it may assume the characters of an air-borne disease, like typhus or measles and attack a considerable proportion of the persons breathing the same air. The adult cases occurred mostly among the artizan section of the population. In such cases of the disease as were recognised the death rate was excessive. Of cases treated to a termination in hospital up to March 31st, 1907, numbering 312 male, 230, or 73.7 per cent., were fatal. Of the total cases 175 were verified bacteriologically and 145 died—82.9 per cent.; 137 were not bacteriologically identified, but on clinical grounds were regarded as cerebro-spinal fever, and of these 85 died, giving a rate of 62 per cent. The outbreak has consisted mostly of single cases in separate households distributed over a wide area. It occurs chiefly in children, and no common centre of infection is discoverable. It may be that the prevalent habit of kissing children is the method by which an organism is transferred to them from the "carrier" cases. At present we know little of the disease clinically, except in its most malignant forms. The disease appears to be diminishing in Scotland, the deaths for the week ending May 25th, being 28, as compared with 39 in the preceding week.

BRIDGE OF WEIR CONSUMPTION SANATORIA AND EPILEPTIC COLONY.—Mrs. Quarrier, the widow of the founder of this charity, writes that the new sanatoria block for 40 patients is now open, giving a total accommodation of 140 beds. The new ward has been alloted to men, and within the next two months it is hoped that there will be provision for children. The recently equipped epileptic colony is fully occupied by 30 male patients, and a donation has been received which will enable Mrs. Quarrier to open a similar one for young women. The Bridge of Weir Sanatorium is one of the best known and best organised charities in Scotland: it originated in an orphan home, and this part of its work still goes on prospering, there being at present 1,320 orphans under Mrs. Quarrier's care. Arrangements are made for settling suitable boys in Canada, and on March 30th a draft of 30 was sent there.

EDINBURGH HARVEIAN FESTIVAL.—The 125th Festival was held in the Royal College of Physicians on May 17th, when the oration was delivered by Dr. Dow, Dunfermline, who selected as his subject "The Evolution of Diseases." After this the annual dinner took place, Dr. Dow being in the chair. Dr. T. S. Clouston is the President-elect.

GLASGOW MEDICAL DISPENSARY.—A department for the treatment of mental diseases has been opened at this dispensary, Dr. Oswald, Superintendent of Gartnavel Asylum, having undertaken to supervise it.

BELFAST.

QUEEN'S COLLEGE.—During the four days from Wednesday to Saturday of last week the students of Queen's College assumed command of the city, and all sorts and conditions of men have been visiting the Athletic Ground Fete at the College. When the scheme for the better equipment of the College proved a success; the students came forward and asked for help to procure a proper athletic ground, and were promptly promised by Sir Donald Currie a quarter of the necessary amount, £5,000, if they could raise the remainder. Further, he gave them a piece of advice: to get the ladies to help them, and every married medical man in the city knows how well they have acted on the advice, for our wives have spent their time and our money without stint. The Fete was opened by Mrs. Wisely, Sir Donald Currie's daughter, the Marchioness of Londonderry presiding. The latter lady made an eloquent appeal for help, urging the necessity for a due consideration for athletics in the Collegiate life, and especially for cricket. On the second day the Fete was opened by the Dowager Marchioness of Dufferin, who delighted her audience with a most charming speech, referring to the late Lord Dufferin's long-continued interest in the College, and then to the present needs. Though the weather has been at its worst, ruining the outdoor entertainments, the Fete has been a great success, and promises to attain the object aimed at.

The Health of the City.—Dr. Gardner Robb believes that the worst of the epidemic of cerebrospinal meningitis is now over, as the number of cases is becoming steadily less each week. The deaths during the past quarter have been 154; 94 males and 60 females. This preponderance of males over females was entirely in the first five years of life, for between 5 and 20, 34 males died, and 37 females. The total deaths over 20 were only 19, and only 1 was over 40. No less than 83 of the deaths occurred after not more than three days' illness. The prosecutions begun by the authorities for breaches of the public health by-laws continue, and will no doubt in time do much good. Last week a publican was fined for keeping milk for sale in a vessel which was not thoroughly clean. Other summonses were for keeping pigs less than 15 ft. from a dwelling-house, and for carrying rubbish in a milk-cart.

Belfast Water Supply.—It may be remembered that when suspicion was thrown on the water supply of the city some months ago by Professor Symmers, Professor of Bacteriology in Queen's College, owing to some bacilli of the typhoid group which he had found in the water, several experts were hastily summoned from England to examine the water on behalf of the Water Commissioners. The chief of them was Professor Percy Frankland, whose report has just been made public. He "goes" in a manner more warmly human than coldly scientific for Professor Letts, of Queen's College, who gave evidence before the Health Commission on the water supply. He says that that evidence is based wholly on chemical standards, which might have held twenty-five years ago, but which have been profoundly modified by bacteriological science. Professor Letts replied in the next day's papers that he would answer fully later, but meantime wished to say that he was a chemist, and never professed to give anything but a chemical view of the question, and that from that point of view the water was far from satisfactory, and as for the modernity or otherwise of methods of examination, he pointed out that perhaps Professor Frankland was not quite as modern as might be expected, for his bacteriological examination took account of numbers only, and had no reference to the species of organisms found, and whether they had any relation to sewage pollution! It is a pretty scientific duel, and will be followed with interest by the medical profession in the city.

LETTERS TO THE EDITOR.

A PERINEAL HORN.

To the Editor of The Medical Press and Circular.

Dear Sir,—Messrs. Fannin and Co., of Dublin, have made to my design a simple instrument which may be called a perineal horn. It is practically the principle of the shoe-horn reversed. I have put it to many tests, and am convinced that by its use rupture of the perineum will become a complication of much less frequency. In every case in which it has been used, the perineum has never caused the slightest anxiety, and needles and sutures are now omitted from my midwifery bag.

The action of a perineal horn is that of a protector to the material tissues and a distributor of the pressure over the internal surface, preventing that initial rupture of the posterior wall of the vagina of which the perineal tear is only the outward and visible sign.

It will be observed that the rent generally takes place after the birth of the forehead, and occurs simultaneously with the elastic rebound of the perineum.

The perineal horn inserted between the child's face and the posterior vaginal wall takes all undue strain off the tissues, internal and external, and equalises the pressure, and affords a smooth surface along which the child's face glides. By manipulation, the pressure on the thinned outer margin of the perineum can be transmitted posteriorly.

I am, Sir, yours truly,

John F. Elliot, L.R.C.P. and S.I.

Indian Medical Officer, Verulam, Natal, S.A.

THE INTERNATIONAL NURSING CONFERENCE.

To the Editor of The Medical Press and Circular.

Sir,—The International Nursing Conference, to be held in Paris on June 18th, 19th, and 20th, organized by the International Council of Nurses, is already an assured success, and must do much to promote the *entente cordiale* between French nurses and those of other nations. Many distinguished nurses from Great Britain and Ireland and her Colonies, Germany, Holland, Denmark, Finland, and the United States of America, have signified their intention of being present, and eminent French men and women in the medical and nursing worlds are taking much interest in its organisation. Mons. Mesureur, Directeur de l'Administration Général de l'Assistance Publique, which controls 20,000 nurses in the Paris Hospitals, will, as President, open the first session of the Conference, with an address on "The Work of the Assistance Publique for Nursing Education." He will be supported by Dr. Bourneville, a veteran worker in connection with the laicisation of nursing in France; Mme. Alphen Salvador, who has established a training school for nurses in Paris on modern lines; Dr. Lande, Administrator of Civil Hospitals in Bordeaux; and Dr. Anna Hamilton, whose notable "Thesis on Nursing," is arousing the most earnest consideration for the care of the sick all over France.

Other Sessions of the Conference will deal with (1) "The Practical Training of Nurses," when Mrs. Bedford Fenwick, founder of the International Council of Nurses, will preside. (2) "The Public and Social Responsibilities of the Nurse." (3) Most interesting sessions will be those on "Professional Organisation," and the "History of the Professional Nursing Press." (4) "International Reciprocity." In all these sections various papers will be read and discussed.

The members of the Conference will be received by the Municipal Council of Paris at the Hotel de Ville, by Mons. Mesureur at the Salpêtrière Hospital, and at Chantilly by the Baroness James de Rothschild, and other invitations to visit hospitals and kindred institutions have already been received.

I am, Sir, yours truly,

M. Breay,

Hon. Treasurer.

431, Oxford Street, London,
June 1st.

THE ALCOHOL MANIFESTO.

To the Editor of the Medical Press and Circular.

Sir,—I am much obliged to Sir Edwin Perry, the Superintendent of Guy's Hospital, for pointing out a slight error in my letter of May 15th.

In the figures I quoted from the *Westminster Gazette* in proof of the declining use of wines and spirits at our general hospitals, it is interesting to note that these figures "relate to alcohol supplied to patients only."

The scientific value of this correction is of great importance to us as it distinctly separates the regulated prescription of alcohol for the treatment of disease, which I hope we all approve of, from the indulgence of "alcoholic drinks" day by day as a beverage. The profession does not manifest its approval of this even in moderation.—I am, Sir, yours truly,

F. Churchill, M.D., F.R.C.S.

Cranley Gardens, Queen's Gate, May 31st.

HOSPITALS AND THE WORKMEN'S COMPENSATION ACT.

To the Editor of the Medical Press and Circular.

Sir,—In cases where the insured is taken to a hospital for medical treatment, may I enquire if the hospital will not be entitled to claim the amount the Insurance Company will have contracted to pay for such medical treatment? I am, Sir, yours truly,

J. H. Carson,
A Governor of The Prince of Wales' General
Hospital, Tottenham.
26, Welbeck Street, London, W.

OBITUARY.

MAXWELL T. MASTERS, M.D. St. And., M.R.C.S., L.S.A.

We regret to announce the death of Dr. Maxwell Tylden Masters, of Ealing, from heart failure following pneumonia. Born at Canterbury in 1833, he was educated at King's College, London, and was admitted a licentiate of the Society of Apothecaries in 1854 and a member of the Royal College of Surgeons, England, in 1856. In 1862 he took the M.D. degree at St. Andrews, and from 1865 till 1868 was lecturer on botany at St. George's Hospital. He was also examiner in botany at the University of London. It was, however, by his connection with the *Gardeners' Chronicle*, of which he was editor for forty-one years, and his contributions to botanical literature, that he was best known. Dr. Masters was an Associate of King's College, a Fellow of a number of learned societies, including the Royal and the Linnean, was an Officer of the Order of Leopold, a corresponding member of the Institute of France, and an honorary or corresponding member of the principal horticultural societies of the Continent and America.

SPECIAL ARTICLE.

DROITWICH.

OPENING OF ST. ANDREW'S BRINE BATHS EXTENSION.

Droitwich was *en fête* on Saturday last, and with good reason. A further and more decided step forward has been taken in the development of the natural therapeutic resources of the town by the erection and equipment of large additional accommodation at the St. Andrew's Baths, and it was to celebrate the completion of this task that a large number of representative medical men, distinguished visitors, and pressmen were made the guests of the Mayor and Corporation. Everything that hospitality could do to make the visit a pleasant one had been thought out by the entertainment committee, and Droitwich and the surrounding country were, if the weather be excepted, seen under the most favourable circumstances. Most of the guests arrived on the Friday afternoon, and were comfortably housed in the various hotels; the rest came on Saturday in time for the opening ceremony. The latter was performed by the Earl of Coventry, who, in the course of his speech, remarked specially on the fact that whereas medical men send numbers of their patients to foreign spas, they seem chary of recommending similar establishments in their own country. The baths having been formally opened and a silver key in commemoration of the occasion presented to Lord Coventry by the Mayor, a very large company sat down to an excellent and particularly well served luncheon in the Salters' Hall. Among those present were the Earl of Coventry, Viscount Cobham, Mr. Cecil Harmsworth, M.P., Member for the Droitwich Division, Mr. Willis Bund, Chairman of the Worcestershire County Council, Mr. R. H. Amphlett, K.C., Recorder of Worcester, the Mayor of Abergavenny, Dr. de Havilland Hall, Dr. Hamilton Cumming, Dr. Shirley Jones, Dr. Robert Collie, Dr. Leonard Williams, Dr. Frank Collie, Dr. Foulds, and a large number of members of the Balneological and Climatological Society. After the usual loyal toasts Dr. de Haviland Hall proposed "Success to Droitwich," and mentioned that he and other London physicians who had had experience in their practice of the effect of Droitwich brine baths in certain rheumatic and gouty affections, entertained a high regard for them. Several of the other speakers dealt on the fact that Droitwich seemed to them to be insufficiently known to the medical profession, and they urged that the many advantages to be derived by invalids from a sojourn there should be brought more directly under the notice of practitioners. Dr. Shirley Jones, who replied for the local profession, dwelt on the general tonic and rejuvenating effect of the baths, particularly in elderly people. Many of the guests proceeded to put this advice to the practical test, and the baths were largely patronised by representatives of medicine and the press. Others took advantage of the opportunity given them by the Humber Company of seeing the neighbourhood. This enterprising firm sent over for the occasion four of their new type of motor-cars designed specially for medical men. The car is admirably adapted for the particular purpose for which it is built, all the requirements of a doctor being catered for in ingenious fashion. It is of 10-12 h.p., and runs with a smoothness and absence of vibration which contrast very favourably with the uneasy motion of many small cars of other types. All who used the Humber cars were enthusiastic in their praise, and we ourselves do not remember to have seen so many advantages combined in one car of moderate price.

A visit to Droitwich is something of an education both in history and in therapeutics. The town was well known to the Romans, but whether it served them as a bathing-station or as a salt manufactory is not known, but the remains of two Roman villas are still present to attest the importance of the neighbourhood in the opinion of the most pragmatical of nations. It is certain, however, that the Saxons recognised the commercial value of the brine, as in 816 a.d. Kenulph, King of Mercia, endowed the church at Worcester with ten salt furnaces at Droitwich, and all through the middle ages the industry of evaporating brine for the recovery of salt was carried on. The fact that there are medicinal virtues in the water was not recognised till 1832, and, curiously enough, it was Sir Charles, then Dr., Hastings, the founder of the British Medical Association, who was instrumental in founding the Royal Brine Baths. Since then there have been several enlargements and developments, but they have all been on a comparatively small scale, and the celebrations on Saturday last, it may be hoped, mark the inauguration of a new era in Droitwich history. For in its own way there is no spa in this or any European country with which Droitwich comes into competition, the nearest approach to its balneological advantages being presented by the Dead Sea, and the waters even of that notorious spot contain only a quarter of the amount of solid constituents that the brine of Droitwich possesses. Droitwich, then, is a spa *sui generis*, and while Harrogate may suit this sufferer, Homburg that, and Vichy the other, Droitwich is adapted by its unique resources for a special class of patient which is reached by none of them, and for that class it is invaluable. Droitwich brine contains the enormously high proportion of 22,250 grains of total salts to the imperial gallon, nearly 22,000 of which consist of sodium chloride, the bulk of the remainder being sulphates of soda and lime. The specific gravity is so high that in the hot swimming-baths the bathers float with the body and limbs raised well above the surface of the water, and in ordinary swimming the legs merely beat the air. A person can easily stand upright in the deep water without performing any movements except such as prevent his feet coming to the surface. What the "molecular bombardment" of such a water must be we can only faintly conceive, but if the ions in normal sodium chloride solution are a state of briskness, in Droitwich water we must suppose that the bather is exposed to a whirlwind of anions and kations compared with which the bombardment of Cronje's camp on the Modder River would be child's play. As the result of experiment it may be said that the sense of *bien-être* conferred by a brine bath is as unmistakable as the stimulation of the air of the Alps; as a matter of fact, it may be added that the testimony of invalids from certain affections, such as sciatica, is emphatic.

The St. Andrew's Baths, which it was the purpose of Saturday's function to speed on their way, are held upon trust under the will of the late Dr. Thomas Corbett, and it may be to this fact, or perhaps to the irony of fate, that they are inscribed with the singularly infelicitous motto for a health resort, *Deus pascit corvos*. It is, doubtless, salutary in a general way that the brevity of life should be kept before our eyes, but there are certain stages in chronic illness when such a thought is apt to have a depressing effect. Perhaps the trustees might be persuaded so to adapt the motto as to suggest the idea that the crows are intended to be employed on similar eleemosynary errands to those they carried out for Elijah when he lay by the brook Kedron.

REVIEWS OF BOOKS.

RECENT WORKS ON DISEASES OF CHILDREN.

The title of this work (*a*) gives a very inadequate idea of the nature of its contents, for it is really a wonderfully complete and able monograph on the subject with which it deals. The various diseases met with by the physician in children are accurately described, and stress laid on the differences which they present from similar diseases as they affect the adult. That this is necessary is soon impressed on anyone who has to deal with such a disease, for instance, as rheumatism in children. We think it a pity that the author has not laid more stress on eye-strain as a cause of disease in children. It seems to have been abundantly proved that many cases of migraine and epilepsy are greatly benefited if not cured by correction of errors of refraction, yet the condition is not even mentioned in connection with the latter disease. A description of the condition known as *status lymphaticus* might also have found a place in this edition, for it is one with which every physician dealing with children should be familiar, even though its recognition has up to the present been chiefly *post mortem*. We point out these deficiencies not in any captious spirit or with any desire to detract from the many merits of the book, but with the hope that they may be rectified in future editions which we have no doubt will soon be called for.

We have received from Messrs. Lippincott the fifth edition of Professor Rotch's well-known work on the diseases of children. (*b*) The book has been re-arranged and re-written, the principle alterations being made in the sections dealing with the care of premature infants, infant feeding, diseases of the gastro-intestinal tract, diseases of the nervous system, rheumatic fever, and the acute and chronic affections of the joints. Twenty-eight new photographs and radiographs have been added. Professor Rotch's work is such a standard authority on all things connected with the management of children in health and disease, that we need say nothing further about the present edition save that it more than maintains the high reputation possessed by its predecessors.

Messrs. Lippincott have also sent us a new work on the diseases of children (*a*) by Dr. A. C. Cotton, Professor of Pediatrics in the Rush Medical College, University of Chicago. This book although of considerably smaller size than is that by Professor Rotch, still contains a large amount of information on the different subjects with which it deals. The book is divided into two parts, the first of which treats of the anatomy, physiology, and hygiene of the developing period, and also contains a chapter devoted to congenital malformations; while the second part is devoted to the diseases of children. The arrangement adopted in the latter part seems to us to be very suitable. The first two chapters deal with diseases of the new-born; Chapters III., IV., and V., deal with disorders of digestion and diseases of the digestive system; Chapters VI. and VII. deal with diseases of the gastro-intestinal tract and of the liver; Chapter VIII. with diseases of the heart and pericardium; Chapter IX. with diseases of the respiratory tract; Chapter X. with diseases of the urinary and genital organs; and Chapter XI. with diseases of the nervous system. Then follow chapters on diseases of the bones and joints, blood, and glands; on the eye and ear; on specific infectious disease; on diseases of the skin; and, lastly, on general diseases such as diabetes and rheumatism. There is also an appendix dealing with sick-room hygiene. Dr. Cotton's style is, on the whole, good, and his manner of expressing himself is clear. His book teems with information, and we can heartily recommend it to all students and practitioners who desire a handy work on the diseases of children. In addition to expressing our approval of the subject matter of the book, we also desire to express our approval of the manner in which the book has been turned out by its publishers. In this respect it is a model of what such a book should be.

ST. BARTHOLOMEW'S HOSPITAL REPORTS (*a*).

This annual volume of reports is always a welcome addition to the library, and one looks forward to finding in it many things both interesting and instructive and, generally, as in the present instance, the anticipation is justified by the result. It is not possible in the space at our disposal to even enumerate the various articles which it contains, but we may safely say that every medical man will find something in it to interest him. Sir Lauder Brunton contributes an interesting communication on the treatment of disseminated sclerosis by full doses of sulphates. He was led to this idea by observing the similarity of the toxic action of some of the benzine compounds on frogs with the symptoms of sclerosis in man, and the slight toxic action of the sulpho-carbolates. He has not yet had sufficient opportunity of testing the treatment to enable him to speak dogmatically about it, but in the two cases in which it has been tried very marked improvement followed. Sir Lauder publishes his cases in hopes that others will give the treatment a trial, since it is simple and at all events can do no harm. Dr. Elmslie, in a very interesting paper, deals with the continuation of active rhachitic processes in the bones into the adolescent period and records three cases in which active rhachitic processes were present in the bones at the ages of nine, fourteen and fifteen years respectively. The diagnosis in these cases was established by X-ray examination of the bones. The paper also contains a tabulated list of the recorded cases. The statistical tables of the patients treated in the wards of the hospital during the year 1905 are issued with the volume.

ANÆSTHETICS (*a*).

When Dr. Blumfeld's little book on anæsthetics appeared in 1902 we were able to accord it high praise. The second edition is now to hand, and it presents certain improvements. There is a fuller account than formerly of the various forms of chloroform inhaler, and there is also an account of ethyl chloride as a preliminary to ether. We are glad to note that ether is recommended to the beginner as the routine anæsthetic agent, and the dangers of chloroform are properly emphasised. These are points to which we have not always been used in the writings of authorities on the subject. In spite of his cautious attitude Dr. Blumfeld recommends chloroform in the extraction of a large number of teeth at one sitting; although experience will seem to be against the administration of chloroform under any circumstances for dental operations. Again, although (page 82) chloroform is prohibited for operations on tonsils and adenoids, at a later part of the book (page 98) it is recommended for operations on the nose, *with the patient in the sitting position*; this seems to us to be courting disaster. On the whole, however, the author's advice may be safely followed. His directions are clear, precise and practical. His writing, if not always in unimpeachable literary style, is at any rate not ambiguous, and we know no book more likely to be of use to the student or practitioner who requires a concise guide to ordinary anæsthetic work.

A SYSTEM OF MEDICINE. (*b*)

The first part of the second volume of the new edition of Allbutt and Rolleston's "System of Medicine" commences with an article by Professor James Ritchie, "on the General Pathology of Infection." This is followed by the continuation of the series of articles on "Infective Diseases of Established Bacteriology," which commenced in Volume I. These articles deal with glanders and farcy, anthrax, tuberculosis, streptothrix infections, actinomycosis, and syphilis, and are contributed respectively by Professor Sims Woodhead, the late Dr. John Bell, and Dr. Legge, Dr. Sidney Martin, Mr. Foulterton, Dr. Acland, and Mr. Jonathan Hutchinson.

The infective diseases of established bacteriology are followed by a further series of articles dealing with "Infective Diseases of Doubtful Nature." These articles deal with measles, German measles, scarlet fever, chicken-pox, small-pox, typhus fever, infectious coryza, whooping-cough, mumps, glandular fever, rheumatic fever, and the acute rheumatism of childhood, and are followed by others dealing with fevers communicable from animals to man. Amongst the contributors we notice the names of Dr. Dawson Williams, Sir John Moore, Dr. Eustace Smith, Dr. Acland, and Sir John McFadyean.

The last 200 pages of Part 1 are occupied by articles on "The Intoxications," and these deal with food poisoning, grain poisoning, alcoholism, opium, and other intoxicants, and metallic and other poisons.

The second part of Volume II. is issued as a separate volume, and is entirely new in arrangement and largely so in substance. All the tropical diseases and animal parasites have been grouped together, with the intention of forming a complete work on tropical medicine. In order to make the volume more complete special articles by well-known zoologists have been included.

This volume commences with an introduction by Sir Patrick Manson. Next comes a series of zoological articles on protozoa, mosquitos, blood-sucking flies, flies known to be concerned in the spread of disease, and ticks. Following this comes a lengthy series of articles dealing at considerable length with tropical diseases. The articles are contributed by, amongst others, Lieutenant-Colonel Leishman, Professor Thayer, Professor Ronald Ross, Dr. L. Sambon, Sir Patrick Manson, Dr. Andrew Davidson, Sir Joseph Fayrer, and Dr. Phineas S. Abraham. The volume closes with a series of articles on Animal Parasites and the Diseases they Cause, and includes such subjects as psorospermosis, worms, and hydatid disease.

There can be little difference of opinion as to the great improvement which the editors have effected by dividing Volume II. into two parts and by the system of rearrangement which they have adopted. The entire work is a notable addition to British medical literature and redounds to the credit of its editors and contributors.

THE SURGERY OF THE RECTUM. (*b*)

The "Surgery of the Rectum" is undertaken by Mr. Wallis, the author, with the idea of presenting this subject in a practical and condensed form for the guidance and help of young surgeons and practitioners.

The work is divided into thirteen chapters. The first five of these, the writer states in his preface, are his original views of the cause and treatment of most of the inflammatory affections in and around the anus. These chapters discuss ano-rectal ulceration, pruritus ani, anal fissure, ischio-rectal abscess, and rectal fistula. Over 90 per cent. of cases of pruritus ani are due to small superficial ulcers below the internal sphincter, which when treated by cauterization cause a rapid disappearance of this troublesome condition. Chapter VI. deals at some length with hæmorrhoids. Of palliative methods of treatment, Mr. Wallis considers that an injection into the pile of 3 to 8 minims of 10 per cent. carbolic acid in glycerine and water is perhaps the best. Whitehead's operation is described fully in the text as being the only radical treatment for hæmorrhoids. Chapters VII. to X. are devoted to prolapse, ulceration, strictures, and growths in the rectum. Chapters XI. and XII. describe the operative procedure in excision of the rectum and in colotomy. The last chapter is a short one on the diagnosis of rectal disease.

"The Surgery of the Rectum" contains short clinical histories of cases, exemplifying symptoms accompanying the diseases described. This constitutes a useful feature in the book. The work is remarkably free from anatomical and pathological details, which doubtless is an advantage when brevity is an object in view. This omission is in a great measure compensated for by a number (55) of very excellent diagrammatic drawings and illustrations by Miss E. Stone, and by Mr. S. A. Sewell, the well-known pathological artist. They very graphically portray the appearances and anatomical situations of various morbid conditions and operative procedures.

Medical Societies' Conversazione.

The Medical Society of London last week at its rooms in Chandos Street, Cavendish Square, gave a reception which was attended by fellows and members and their visitors to the number of about 200. In the absence through illness of the President, Mr. C. A. Ballance, the guests were received by Sir John Tweedy and Sir Edgcumbe Venning, of whom the first named made sympathetic reference to the loss sustained by the society through the death of Sir Joseph Fayrer, one of its most distinguished past presidents. Following the custom which has prevailed for a century the oration, which is delivered in alternate years by physician and surgeon, was given by Dr. George A. Gibson, taking for his subject "The Cause of the Heart Beat." A highly successful conversazione with music followed.

(*a*) Medical Monograph Series, No. 7. "Anæsthetics: A Practical Handbook." By J. Blumfeld, M.D. (Cantab.). Second Edition. London: Bailliere, Tindall and Cox, 1906. Pp. 117. Price 2s. 6d.

(*b*) "A System of Medicine by Many Writers." Edited by Professor T. Clifford Allbutt, M.D., F.R.S., Regius Professor of Physic in the University of Cambridge, and H. D. Rolleston, M.D., Physician to St. George's Hospital, and to the Victoria Hospital for Children. Vol. II., Part I, pp. xii. and 1087; and Part II., pp. xvi. and 1,055. London: Macmillan and Company, Limited. 1907.

(*a*) "Surgery of the Rectum." By Fred C. Wallis, B.A., M.D., B.C.Cantab., F.R.C.S., Surgeon to Charing Cross Hospital, St. Mark's Hospital, and the Grosvenor Hospital for Women and Children. London: Bailliere, Tindall and Cox. 1907. Pp. viii. and 168. Price 6/- net.

Weekly Summary of Medical Literature, English and Foreign.

Specially compiled for The Medical Press and Circular.

RECENT GYNÆCOLOGICAL LITERATURE.

Prophylaxis and Treatment of Post-operative Phlebitis.—Brothers (*Amer. Jour. of Obst.*, May, 1907). Strictly speaking, we cannot dissociate phlebitis and venous thrombosis, both together constitute the clinical entity which we ordinarily understand as post-operative phlebitis. An injury to a vein is the most frequent direct cause of phlebitis; whereas the absorption of septic fluids from contiguous structures that are septic is the common indirect cause. Thrombi result from alteration of the endothelium of the vein in the vast majority of cases; accessory causes include the presence of micro-organisms and their products in the blood; clots carried from other parts and acting as foreign bodies; necroses, gangrene, inflammatory and degenerative processes occurring in and about the vessel walls. The Mayos and others believe that inaction due to prolonged rest in bed, combined with low blood pressure, plays a very important *role* in the ætiology of post-operative phlebitis. Excluding direct injury to a vein or its involvement as a result of cellulitis in its vicinity, we face two conditions in the study of the prophylaxis of post-operative phlebitis, sepsis and blood retardation. Next to asepsis comes the question of the importance of rest in the prophylaxis of post-operative phlebitis. Given a case of suppurative appendicitis or adnexitis with a drained wound, we are unanimous in advising rest in bed. Beyond this point we reach the "parting of the ways." "If, after an aseptic operation with closure of abdominal incision without drainage, the surgeon is convinced that:—phlebitis always precedes and induces thrombosis, the only safe rule is to keep his patient in bed during the time which this complication is likely to occur, two or three weeks. If, on the other hand, one feels in this class of cases retardation of the blood current is one of the chief factors in producing coagulation, and, later, thrombosis and phlebitis, and questions the possibility of infection after aseptic work, the logical indications will be early movement and early removal from bed. After reviewing the statistics and reports of Ries, Boldh, and Hertoz from Landau's clinic in Berlin, the author summarises as follows: (1) Careful asepsis and antiseptic detail; adequate drainage in purulent or infected conditions, using the Fowler position to carry out this end. (2) In aseptic, non-purulent intra-abdominal conditions which are submitted to other than fixation operations, the occurrence of post-operative phlebitis will be reduced in frequency by getting such patients out of bed before the end of the first week. In regard to the treatment of phlebitis, rest, elevation of the affected limb, and an icebag meet the indications. F.

Mesosigmoiditis and its Relations to Gynæcological Affections.—Emil Ries (*Amer. Jour. of Obst.*, May, 1907). Mesosigmoiditis is a condition of chronic inflammation of the connective tissue, as well as the peritoneal covering of the mesentery of the sigmoid flexure. This chronic inflammation leads to shrinking of this mesentery and shortening of the base of the mesosigmoid. The sigmoid is thereby hindered in its normal free excursions, and becomes a fertile source of grave and sudden danger. Of the causes of this condition, two are firmly established in the ætiology—one the so-called Groser's diverticula in the sigmoid, the other, chronic inflammatory conditions extending from the neighbouring structures, particularly the rectum and the female sexual organs. Fæcal matter entering Groser's diverticula, stagnates there and may lead to inflammation, ulceration, and sometimes even perforation. The consequence of the absorption of septic material from these diverticula is the cause of the chronic inflammation of the meso-sigmoid. Mesosigmoiditis by extension of inflammation occurs in connection with prostitis, stricture, or ulceration of the rectum, chronic inflammation of the left appendages, or of the tumours of the latter leading often to adhesions of these organs to the mesosigmoid. The symptoms are not, as a rule, very marked; they consist mainly of constipation, flatulency, and more or less pain in the region of the sigmoid. Patients often complain of a feeling of stiffening in the bowel, localised bloating, with acute sharp pains in this locality. But, as a rule, the symptoms are not sufficient for a reliable diagnosis, until, perhaps, a typical ileus develops, due to volvulus of the sigmoid to which the mesosigmoiditis has given the predisposition, and then the patient's previous history becomes illumined by the pathological condition found in the operation for relief. F.

Induction of Labour in Prolonged Pregnancy.—McKerron (*Jour. Obst. and Gynæco.*, May, 1907.) Making allowance for possible errors of calculation, there would seem to be no doubt that the duration of pregnancy exceeds the physiological limit of 285 days in about 2 or 3 per cent. of cases. When pregnancy is unduly protracted, effects are produced which have an unfavourable influence on the course of labour, and which involve increased risk for both mother and child. (1) The child is longer and larger than normal. (2) The circumference of the head is usually greater, while the cranial bones are unduly ossified and do not mould so readily as in the normal fœtus. (3) In excessive intra-uterine development the shoulders, as pointed out by Herman, are larger in comparison with the head than is normal. Owing to the difficulty of extraction, the child is liable to be lost, but death not infrequently occurs *in utero* before the onset of labour. A possible explanation of this is that the thrombotic changes in the placenta, which normally precede labour, may become so advanced as seriously to interfere with the fœtal circulation and lead to the death of the child. Prolonged gestation presents danger to the life of the mother, from over-distension of the uterus and fatty degeneration of the uterine walls, leading to uterine inertia, and tendency to post-partum hæmorrhage. The treatment consists in the induction of labour, where there is clear evidence that pregnancy has exceeded the physiological limit, and that its further continuance may lead to serious difficulties. F.

Paralysis of the Intestine with Regurgitant Peristalsis following Delivery.—Robert Jardine (*Jour. Obst. and Gynæco.*, May, 1907). The writer records a case of very difficult forceps delivery occurring in a four-para, æt. 28, full time. The retraction ring was apparent, and the child weighed 9¾ lbs. The day after delivery the patient was sick, and vomited some dark-coloured bilious material. She complained of abdominal pain, and there was considerable distension, especially of the stomach and colon. Urine was passed involuntarily, the bowels did not act. The temperature ranged from 99° to 99.8.; pulse 84-110. Next day the vomiting was incessant, of a dark material, with a faint fæcal odour. The abdomen was much distended, rigid, and painful on pressure. Temperature, 97.6°—98.2°., and the pulse 92—116. The stomach was washed out every third hour with normal saline solution, and several basinfuls of dark pultaceous material with an admixture of bile and altered blood were flushed out at first; at the fourth washing the fluid was comparatively clear. A turpentine enema had no effect, but in the evening flatus was passed freely and a well-formed motion. On the third day the patient was much improved, there was no sickness, and abdominal distension had decreased. Henceforth the recovery was rapid. The general treatment adopted consisted of a turpentine enema daily, linseed-meal poultices to relieve pain, champagne half-ounce hourly, strychnine hypodermically 1-60th gr. every fourth hour, nutrient enemata, and peptonised milk was begun on the fourth day. By the sixth day she had regained complete control over her bladder. F.

A Contribution to the Operative Treatment of Chronic Inflammatory Diseases of the Adnexae through Ventral Laparotomy is made by Esch (*Zeitschrift für Geb. und Gyn.* Bd. LIX, Hft. 1).—Patients suffering from these diseases are only operated on in Olshausen's Klinik when all conservative methods of treatment have failed. In cases of pyosalpinx the period since infection must be about nine months. The removal of the diseased adnexae is accomplished either by first tying off the broad ligament with three ligatures, or according to Henkel's method by which the interstitial portion of the tube is extirpated, and the mesosalpinx immediately under the tube is cut through, then after ligature of the ovarian artery the peritoneal wound is closed with a continuous catgut suture. Flushing out the abdominal cavity is never practised, even when it has been soiled by pus. It is important that the field of operation should be made as dry as possible before the abdomen is shut. In the 2½ years from January 1st, 1904, to June 31st, 1906, 83 women were operated on, 63 on account of unilateral or bilateral pyosalpinx and 20 for hydrosalpinx or simple salpingitis. Among the cases of pyosalpinx, there was no rupture of the tubes during removal in 23 patients, and the mortality was nil. Rupture occurred in 40 cases, 12 of those being complicated with ovarion abscesses. Among the 28 cases which were not thus complicated, there were five deaths of which two may be accounted for by the infection of the peritoneum by the pus. For only two patients was drainage adopted. They both recovered. The mortality among the 83 cases was 7.2 per cent. When one compares both methods of operation as regards exudate formation, having added the 20 cases operated on for non-purulent disease, in 53 cases with stumps projecting into the peritoneal cavity, exudates arose 17 times, while among 21 operated on by Henkel's method, an exudate could only be discovered in one case. G.

Diffuse Adenoma of the Myometrium.—According to Schütze (*Zeitschrift für Geb. und Gyn.* Bd. LIX, Hft. 1) the diffuse deep adenomatous new-growths in the myometrium are so rare, that there are only 14 cases on record. In this paper the author describes three new cases. The age of the patients varied between 46 and 50 years. Two had had several confinements One was a nullipara. Two of them suffered from profuse metrorrhagia, and one from severe menorrhagia. Repeated curettage only succeeded in temporarily lessening the hæmorrhage, although microscopical examination revealed each time nothing but benign hyperplastic endometritis. Definite cure could only be produced by extirpation of the diseased organs. The author comes to the following conclusions. Deep diffuse endometrial growths in the myometrium of old women produce a definite disease of unknown ætiology. The severe clinical symptoms require extirpation of the diseased organ. Anatomically it consists of an infiltrating and destructive growth of hyperplastic mucous membrane into the peripheral layers of the myometrium. Even though neither extension into the neighbourhood of the uterus, nor the formation of metastases have so far been observed, one must consider this morphologically benign overgrowth of the endometrium as a serious disease, and as an early stage of adeno-carcinoma of the uterine body wall. G.

Experiments Regarding Artificial Sterilisation of Women are recorded by Offergeld (*Zeitschrift für Geb. und Gyn.* Bd. LIX, Hft. 1.)—The experiments were conducted on bitches, cats, and rabbits, who at the time of experiment were certainly not pregnant. After opening the abdomen the tubes were ligatured, or they were cut through or crushed with or without the addition of a catgut or silk ligature. Healing followed in every case without disturbance. At the succeeding rut the animals were paired and kept under observation to see if pregnancy ensued. The results were that none of these procedures were sufficient to prevent conception. The only certain method of sterilisation is to remove the tubes completely having resected the interstitial portions from the uterus. The openings so produced must then be closed carefully. G.

Pseudo-Carcinomatous Infiltration of the Intestinal Wall with Inflammatory Diseases of the Adnexae.—Füth (*Monatssch für Geb. und Gyn.* Bd. 25, Hft. 3) describes a case in which during a laparotomy for tumours of the adnexae a great thickening of the intestinal wall was revealed which was thought to be carcinomatous. Examination afterwards showed that it was only an infiltration of the intestinal wall. In a second case there was in addition to a myomatous uterus, and a tumour of the right ovary and tube, a tumour the size of a pigeon's egg in the sigmoid flexure. It was considered to be carcinomatous and was removed. Microscopical examination of the resected portion of the intestine proved it to be only a small celled infiltration. In a third case the author operated on a left-sided pyosalpinx which was firmly adherent to the sigmoid flexure. The latter was most suspiciously infiltrated in quite a circumscribed manner. Remembering the former cases the author decided not to resect the intestine. Only an appendix epiploica was removed which proved microscopically to be benignly infiltrated. The patient recovered completely after the operation. On the other hand the author relates the history of a case operated on by Sänger, where in the same manner with tumours of the adnexae an infiltration of the rectum was found which at the time was considered to be benign. Three months later carcinoma high up in the rectum was diagnosed. G.

Pubiotomy in Private Houses.—Sigwart (*Zentralbl für Gynäk*, March 20th, 1907) records five cases in which he did this operation among the poor of the extern maternity department of the Charité in Berlin. Three cases were operated on by the light of a kitchen lamp, two in daylight. The first case was a IV gravida without a living child. Conj. vera. 7 cm. a rachitic flat pelvis. Vertex presentation. The indications for operation were prolonged powerful labour, fœtal heart becoming bad, retraction ring rising very high, only a small segment of the head through the brim. The pelvis separated to a distance of 6 cm., the woman delivered herself very easily. The child was 52 cm. long, circumference of the head 36 cm. From the 4th to the 7th day there was a slight rise of temperature. The patient was up after the third week. The second case was a I gravida. Flat rachitic pelvis. Conj. diag. 9½ cm. Labour began at 3 a.m. December 10th, 1906. Membranes ruptured at 5 p.m. December 11th. Vertex presentation. Head mobile above the brim in spite of very strong contractions. 7.30 p.m. pubiotomy. The pelvis separated at first 2 cm., but during the pains as the head descended it separated 4 cm., only to close up again after the pain ceased. At 2 a.m. next morning the patient delivered herself. Child 51 cm. long, circumference of head 36 cm. Puerperium free from fever except for a temp. of 38.9 on the evening of the sixth day. The patient, who got up on the twentieth day, walked to the hospital on the twenty-fourth. Third case, a II gravida. First child dead after three days labour. Rachitic flat pelvis. Conj. diag. 9 cm. After very prolonged labour, as the mother's temp. was 38.5, pulse 110, and the liquor amnii was smelling badly, pubiotomy was performed as only a very small portion of the head had moulded through the brim. The child was delivered with forceps. In this case, during the puerperium an abscess developed which pointed at the left side of the posterior wall of the vagina. When it was emptied the patient rapidly recovered. The fourth case, a V gravida. The third child was delivered with high forceps and still lives. The others were stillborn. Rachitic flat pelvis. Conj. diag. 9 cm. In spite of very powerful labour the head did not enter the pelvis, and as the fœtal heart fell to below 100, pubiotomy was performed. The child was delivered with forceps. Convalescence uneventful. The fifth case, a IV gravida, without a living child. The first child was perforated, the second pregnancy ended in abortion at the fourth month. The third child was perforated. Flat rachitic pelvis. Conj. diag. 9 cm. Transverse presentation. Pubiotomy was performed, and the child turned and extracted. Puerperium uneventful except for an evening temp. of 38. from sixth to tenth day. The patient got up on the twentieth day. The five children were delivered alive, and all survived except the second, which was killed by an accident on the evening of the second day. The women were all able to walk without pain, none of them suffered any pain other than the ordinary labour pains when delivering themselves after the bone was cut. G.

Medical News in Brief.

The Royal College of Surgeons in Ireland—Election of Officers.

The annual meeting of the College was held on Saturday, June 1st, when a very favourable report was submitted to the Fellows. During the year 17 candidates having passed the examinations, were admitted to the Fellowship; 73 candidates, having passed the conjoint examination with the Royal College of Physicians, received the Diploma in Surgery and Midwifery; 29 candidates, having passed the conjoint examination with the Royal College of Physicians, received the conjoint diploma in Public Health; 10 candidates, having passed the examinations, received the licence in Dental Surgery; 64 candidates, having passed the conjoint preliminary examination with the Royal College of Physicians, received certificates.

The obituary list showed the death of six Fellows, 51 Licentiates, and 3 Licentiates in Dental Surgery. There are at present living 15 Honorary Fellows, 466 Ordinary Fellows, 2,908 Licentiates, six Honorary Diplomates in Public Health, 269 Ordinary Diplomates in Public Health, and 531 Licentiates in Dental Surgery.

The annual election of officers of the College was held on Monday last, when Mr. H. R. Swanzy and Mr. John Lentaigne were respectively re-elected president and vice-president for a second year. The following were elected on the Council:—William Stoker, Sir Charles A. Cameron, John B. Story, Sir Charles B. Ball, Sir Thomas Myles, Sir Arthur Chance, Richard D. Purefoy, Sir Lambert H. Ormsby, Henry G. Sherlock, R. Bolton McCausland, R. John S. M'Ardle, Robert H. Woods, R. Lane Joynt, Thomas Donnelly, William Taylor, Edward H. Taylor, R. Charles B. Maunsell, William Ireland Wheeler, and D. Edgar Flinn. Among the new candidates which came forward for election were:—Lieutenant-Colonel Edgar Flinn, Mr. Louis A. Byrne, Mr. F. T. Porter Newell, Mr. R. Lane Joynt, Mr. Thomas E. Gordon, Mr. Louis Werner, Mr. H. W. Oulton, Mr. Robert J. Harvey, Mr. Thomas O'Connell Redmond, Mr. George P. Meldon, and Mr. Andrew Charles. Of the existing members of Council, Dr. E. H. Bennett has retired on account of very serious ill-health, and Mr. Jameson Johnston has been elected a member of the Court of Examiners and is consequently ineligible.

Royal College of Surgeons of England—Annual Election.

The annual election to the Council of the College will take place on Thursday, July 4th next. The retiring members of the Council on this occasion are:—Sir John Tweedy, Mr. Mansell Moullin, Mr. Herbert Page and Mr. Frederic Eve. Sir John Tweedy was to have retired in the year 1904, but being president, retained his seat on the Council in accordance with custom until vacating the president's chair. Both Mr. Moullin and Mr. Eve were last elected as substitute members of the Council, the former for the late Sir William MacCormac and the latter for the late Mr. T. R. Jessop. It is understood that Sir John Tweedy does not intend to offer himself for re-election. The other three candidates, however, stand for re-election, and there are at present three intending new candidates, viz.: Mr. Bruce Clarke, Surgeon to St. Bartholomew's Hospital; Mr. Charles Higgens, Consulting Ophthalmic Surgeon to Guy's Hospital, and Mr. W. D. Spanton (Hanley), Consulting Surgeon to North Staffs. Infirmary. Voting papers will be sent to each Fellow of the College without application in the United Kingdom whose address is registered at the college. The poll will be open at the College between the hours of 3 and 5 for personal voters.

The Irish University Bill.

The Prime Minister announced in the House of Commons on Monday night that this contentious measure would be dropped for the present Session, but Mr. Birrell would give special attention to the Irish University question during the recess, with a view to legislation next year.

Asylum Workers' Association.

The annual general meeting of the Asylum Workers' Association, founded in 1895 to improve the *status* of asylum nurses and attendants, and to enlist public sympathy in their work, was held last week at the Medical Society's house, 11 Chandos Street, W. Sir William Collins, M.P., was elected president of the association, and in his presidential address said that he could conceive no calling in which active sympathy was more needful or more helpful, and at the same time, perhaps, more difficult to maintain and to retain and to cultivate, than that of the asylum worker. Asylum workers had by taste or inclination embarked on a calling demanding no mean attainments if their work was to be well done; their services to the State were accordingly ranked high. The State or municipality should see to it that such work was justly recognised and adequately requited. The hours of duty should not be excessive. The strain was great in the acute wards, and the tedium of the chronic demented was no less exhausting. He had done his best in other capacities to foster the scientific study of the pathology of insanity. He carried through the London County Council a proposal for a laboratory at Claybury Asylum, and assisted in equipping it, and he rejoiced that, under Dr. Mott, that laboratory was adding to their knowledge of the dark continent of mental disease. He moved the adoption of the report. The Bishop of Croydon, in seconding, said the insane suffered from morbid sensitiveness and, therefore, it was necessary that they should have nurses and attendants who did their very best, morally as well as physically, to minister to their wants. Two gold and silver medals were afterwards presented by the president for long and meritorious nursing service.

Stauts Lymphaticus.

Dr. R. L. Guthrie, Deputy-Coroner, held an inquiry at Shoreditch, on May 22nd, respecting the death of Frank G. S. Scott, æt. six months, the son of a packer.

The mother stated that the child was one of twins and was perfectly healthy up to Monday. She fed him shortly before six o'clock on Monday morning, and a few minutes later noticed he had changed colour. He died shortly afterwards.

Dr. Rustun Coolawalla stated that he had made a *post-mortem* examination, and he attributed death to an excess of lymphatic growth, which predisposed individuals to death from trivial causes. It was a case of status lymphaticus. In answer to the Coroner witness said that he was of opinion that the child had been partially suffocated. The slightest pressure over the face in such a child would be fatal. The Coroner: From a medico-legal point of view this is very important. A man might be charged with "murder" or "manslaughter" through giving another a slight blow, and the medical man who by chance overlooked this status lymphaticus would be losing a valuable point for the defence. The doctor further stated that a child suffering from the complaint might be killed by being put into a cold bath, and would be more liable to succumb to any slight ailment. The jury returned a verdict to the effect that the child was "accidentally suffocated while suffering from status lymphaticus."

Curious Epidemic at Prestwich.

A DISEASE, which is at present epidemic at Prestwich, is said to be puzzling the medical men there. The illness begins with swelling and soreness in the throat, which causes difficulty in breathing and loss of voice, and the symptoms are accompanied by a rapid rise of temperature, sickness, loss of appetite, and weakness Dr. Stephenson, the medical officer of health for Prestwich, estimates that there are now a hundred and fifty people in that district suffering from the malady. Fresh cases are reported daily, and at least three hundred persons, mostly children, have been attacked. Fortunately the illness runs its course rapidly, and does not appear, if rightly treated, to be fatal. Dr. Stephenson thinks the disease is probably air-borne. Bacteriological tests made at Manchester University show that the ailment is caused by a very minute globular bacillus which settles in the throat, causing irritation and swelling.

Room for Medical Men in South Africa.

So great is the dearth of medical men in South Africa, reports *The Express*, that an advertisement of a vacancy on the resident staff at Kimberley Hospital, carrying a salary of £300 a year, with board and quarters, did not bring a single application.

Royal Medical Benevolent Fund Society of Ireland.

A QUARTERLY meeting of the Central Committee of this Fund was held at the Royal College of Surgeons on Wednesday last, Dr. Richard Hayes in the chair. It was unanimously resolved that the best thanks of the Central Committee be given to Dr. Redmond, President of the Royal College of Physicians, for his generous donation of £21 to the funds of the society.

Hospital for Sick Children, Great Ormond Street, London.

THE following is a list of lectures, which are free to medical practitioners, to be delivered during June and July on Thursdays, at 4 p.m.:—June 6th, Mr. Corner on "Torsion of the Testicle"; June 13th, Dr. Voelcker on "Enlarged Abdomens"; June 20th, Mr. Kellock on "Affections at and about the Umbilicus"; June 27th, Dr. Garrod on "Diabetes in Children"; July 4th, Dr. Still on "Bilious Attacks in Children"; July 11th, Dr. Thursfield on "The Diagnosis, Prognosis, and Treatment of Pleural Effusions in Children"; and July 18th, Mr. Lane on "Fractures."

Women's Health Society.

At Christ Church Vicarage, Forest Hill, at the invitation of Mrs. C. R. Bailey, a number of ladies assembled on May 29th to hear a lecture by Dr. Marion Hunter, one of the London County Council medical inspectors of schools on "The Hygiene of Child-life and its Effect on National Physique." The gathering was arranged under the auspices of the Borough of Lewisham Women's Health Society, the president (Mrs. G. S. Warmington, of Lee) presiding.

The Sanitas Company.

AT the annual meeting of this company, whose disinfectants are so well-known and appreciated by the medical profession held on Wednesday last, the Chairman, Mr. Kingzett, F.I.C., referred to the uninterrupted progress of the company side by side with that of sanitation during the past quarter of a century, the sales of their various manufactures having exceeded those of any previous year. He drew special attention to two recent introductions which he had made, viz.: "Bacto:." a very powerful germicide, having a co-efficiency of about thirteen times that of pure carbolic acid, and "Okol," which he considered the most powerful germicide yet produced, having a co-efficiency on the B. typhosus test of 22 as compared with carbolic acid. It may be added that the company has acquired larger premises in which to carry on their manufactures and that the usual dividend of 7½ per cent. per annum was declared.

PASS LIST.

Royal (Dick) College of Veterinary Surgeons.

AT the recent sitting of the Examining Board of the Royal College of Veterinary Surgeons held at the Royal (Dick) Veterinary College, Edinburgh, the following students passed their several examinations:—

First (or Class A) Examination:—William Aitken, Edinburgh; Haylett Allison, Ballarena, Co. Derry, second honours; J. L. Cormack, Colinton, Mid-Lothian; J. N. Cooper, Ballymoney; S. C. Currey, Workington, second honours; M. G. Fox, Atherstone, second honours; Hugh Fraser, Inverness; J. R. Greig, Leith; J. B. Idle, Harrowgate; R. C. W. Lacey, London; W. S. Lornie, Newburgh, first honours; A. D. McGregor, Edinburgh, second honours; Thomas M'Clintock, Londonderry; C. E. M'Crea, Newry; John Nicol, Markinch.

Second (or Class B) Examination:—John Anderson, Caledon, County Tyrone; G. F. Banham, Cambridge; Frank Chambers, Dudley, Worcester, second honours; D. R. Crabb, New Aberdour; C. S. Hunting, Sunderland; John de Merza, London; W. M. Mitchell, Sunderland; G. T. S. Mower, Sheffield; J. A. M'Menamin, Mayherafelt; E. J. Nicholson, Budlington, Yorks; J. A. Robertson, Sydney, N.S.W., second honours; B. A. Searby, Louth; J. H. Spreull, Dundee; C. G. Thomson, Lurgan.

Third (or Class C) Examination:—William Brown, Banchory; H. D. Gilmore, Kircubbin, Co. Down; Charles Johnstone, Dumfries; J. R. A. Jones, Oswestry; William Kennedy, Whiting Bay, second honours; R. G. Linton, West Kensington, W.; Alex. Matthew, Edinburgh, second honours; R. H. Miller, Edinburgh; J. W. Morron, Coleraine, first honours; John Robson Bellingham, Northumberland; W. P. Ruthven, Kinross; P. T. Saunders, Hull; J. J. M. Soutar, Edinburgh; J. C. Storie, East Linton, Thomas Woods, Preston.

Class D, and were admitted members of the Royal College of Veterinary Surgeons:—James Anderson, Keith, Banffshire; James Andrew, Haddington; W. King Clark, Gullane, East Lothian; Frank Davidson, Gollanfield Jt., Inverness; W. A. Grant, Tomintoul, Banffshire; Peter Haugh, Kirkcudbright; Frank Macdonald, Portobello; J. Gillray McGregor, Greenock; Alex. Mackenzie, St. Andrews; F. W. Medlock, Inverness; Alex. Niven, Rothienorman, Aberdeenshire; Bruce Selous, Birmingham; L. L. Steele, Beckermet, Cumberland; John Taylor, Edinburgh, second honours: Thomas Wilson, Nantwich; A. M. Wylie, Kirriemuir.

The session just ended has been a most successful one, the members of the final year's class especially distinguishing themselves, 100 per cent. obtaining their diplomas; while the passes in the other classes has been exceedingly satisfactory. Students of the junior classes have now mostly left to see practice with veterinary surgeons during the summer, returning again at the opening of next session on October 1st.

A CONSULAR report from the Washington Bureau of Manufactures, contains the following: "The reports of the Public Health and Marine Hospital Service shows that in 1902 there were reported to the Bureau 55,857 cases of smallpox, with 1,852 deaths, while in 1906 there were 12,503 cases, with 90 deaths. The Bureau states that the result is due to increased diligence on the part of State and national authorities. In Germany, where vaccination is compulsory and universal, during the year 1906 there were only 26 cases, with five deaths in the whole empire, and these cases were largely imported."

NOTICES TO CORRESPONDENTS, &c.

☞ **Correspondents** requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Reprints.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

Original Articles or Letters intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessary for publication but as evidence of identity.

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12.

R. H.—It is much wiser not to allow any animal in the room of a patient suffering from scarlet fever. Although no animal is known to suffer from the disease, a hairy animal, such as a pet Yorkshire terrier, might easily convey dried secretions in its coat to healthy children, and we cannot advise you to introduce any such source of danger into a household, even if the child be lonely.

Pestis.—Up to September last the deaths from plague in India (including native States) numbered 5,012,000. For the first three months of this year the numbers are: January, 58,438 deaths; February, 98,397; and March, 171,522. The Punjab, Bengal, Bombay, and United Provinces are those chiefly affected.

R. J. M. (Leeds).—Our correspondent will find all that he desires to know in the last (fourth) edition of Dr. J. A. Shaw-Mackenzie's work on cancer, published by Messrs. Bailliere, Tindall and Cox.

THE DECREASE OF MEDICAL STUDENTS.

Viator.—There appears to be a steady decrease in the number of students entering the medical schools of late; from the *Medical Register* for 1907 we learn that the number of medical men registered last year was only 444, against 545 in the previous twelve months, and 703 in 1901. With one exception (1899) the number was lower in 1906 than in any year during the last decade. The decline has been ascribed to the increased cost of medical education, and the outcry that the profession is overcrowded.

Dr. R. L.—Your letter is unavoidably crowded out "at press"; we hope to have space for it in our next.

Meetings of the Societies, Lectures, &c.

Wednesday, June 5th.

Obstetrical Society of London (20 Hanover Square, W.).—8 p.m.: Specimens will be shown by Dr. Longridge, Mrs. Scharlieb, The President (Dr. H. R. Spencer), and Dr. McCann. Short Communication: Dr. H. R. Andrews: Two cases of Pregnancy in a Rudimentary Uterine Horn. Papers:—Mr. H. T. Hicks: Primary Vaginal Embolic Chorion-epithelioma.—Dr. Griffith and Dr. Williamson: A Case of Chorion-epithelioma complicated by Hæmatometra.

Vacancies.

Dr. Steevens' Hospital.—Anæsthetist. Applications to the Secretary. (See advt.)

Manchester University.—Junior Demonstrator of Physiology. Salary £100 per annum. Applications to the Registrar.

The Hospital for Sick Children, Great Ormond Street, London, W.C.—House Surgeon. Salary for six months £20, washing allowance £2 10s., with board and residence in the Hospital. Applications to the Secretary.

City of London Hospital for Diseases of the Chest, Victoria Park, E.—Resident Medical Officer. Salary £120 per annum, with board, etc. Applications to the Secretary.

Halifax Union Poor Law Hospital.—Resident Medical Officer. Salary £105 per annum, with apartments, rations, and washing. Applications to Arthur T. Longbotham, Solicitor and Clerk to the Guardians, 4 Carlton Street, Halifax.

Corporation of the City and County of Newcastle-upon-Tyne.—Assistant Medical Officer of Health. Salary £300 per annum, with board, lodging, etc. Applications to the Medical Officer of Health, Town Hall, Newcastle-upon-Tyne.

Egypt.—Sub-Inspector of Ophthalmic Hospitals. Salary £500 a year, with two months' salary in lieu of travelling expenses to and from England. Applications to the Director-General, Department Public Health, Cairo.

The Hospital for Sick Children, Great Ormond Street, London, W.C.—An Anæsthetist. An honorarium of 15 guineas. Applications to Stewart Johnson, Secretary. (See advt.)

Royal Albert Hospital, Devonport.—Resident Medical Officer. Salary £100 per annum, with apartments, board, fuel and lights, and laundry. Applications to the Chairman of the Selection Committee.—Chas. W. Dickinson (Capt. R.N.), Secretary, Royal Albert Hospital, Devonport.

Bradford Children's Hospital.—House Surgeon. Salary £100 per annum. Applications to C. V. Woodcock, Secretary, Bradford.

Brixton Dispensary.—Resident Medical Officer. Salary £150 per annum, with furnished apartments, attendance, coal and gas. Applications to the Secretary at the Dispensary, Water Lane, Brixton, S.W.

Appointments.

Bradley, Frederick H., M.B., Ch.B.Edin., Senior House Surgeon at the Liverpool Stanley Hospital.

Costouros, J. M.D., L.M., Clinical Assistant to the Chelsea Hospital for Women.

Crosby, Harry Mair, M.B., C.M.Edin., Honorary Surgeon to the General Hospital, Stroud (Gloucestershire).

Fleury, K. F., L.R.C.P. and S. Irel., Medical Officer for the Riverstown Dispensary District of Birr, King's County, Ireland.

Jubb, Archibald, M.D.Glasg., Extra Honorary Physician to the Royal Hospital for Sick Children, Glasgow.

Morris, William David Joseph, M.R.C.S., L.R.C.P.Edin., L.S.A., Medical Officer to the Cardiff Post Office (Eastern District).

Patrick, J. King, M.B., Ch.B.Glasg., Extra Honorary Physician to the Royal Hospital for Sick Children, Glasgow.

Russell, W. K., M.B.Glasg., Medical Officer and Public Vaccinator for the No. 1 (Ilminster) District by the Chard (Somerset) Board of Guardians.

Sibbald, Ian Graham, M.B., C.M.Edin., Medical Officer of Health by the Chard (Somerset) Rural District Council.

Stevens, Bertram Crossfield, M.S., M.D.Durh., F.R.C.S.Edin., L.R.C.P.Lond., Additional Honorary Anæsthetist to the Lancaster Royal Infirmary.

Treasure, William Beeson Crawford, M.D.Durh., M.R.C.S., L.S.A., Medical Officer to the Cardiff Post Office (Western District).

Vintras, G. C. Louis, M.D.Durh., Director of the French Convalescent Home at Brighton and of the Annexe for the Preventive Treatment of Tuberculosis.

Births.

Caie.—On May 30th, at 76 Guildhall Street, Bury St. Edmunds, the wife of W. J. Caie, M.A., M.B., Ch.B., of a son.

Gadsden.—On May 27th, at Newquay, Cornwall, the wife of A. H. Gadsden, M.R.C.S., L.R.C.P., of a daughter.

Holland.—On May 25th, at Grayswood Pines, Halsemere, Surrey, the wife of Henry F. Holland, M.D., J.P., of a son.

Ormerod.—On May 31st, at Redlands, Burgess Hill, Sussex, the wife of Charles E. Ormerod, M.D., M.R.C.S., of a son.

Schofield.—On May 29th, at 1 Phillimore Gardens, Kensington, the wife of S. Robert Schofield, M.B., of a daughter.

Sikes.—On May 28th, at 8 Manor House, Marylebone Road, London, the wife of Alfred W. Sikes, M.D., D.Sc., F.R.C.S., 57 Wimpole Street, London, of a son.

Marriages.

Fullarton—Page.—On May 28th, at St. Mark's Church, New Brompton, Chatham, Surgeon John Fullarton, M.B., R.N., Royal Marine Head Quarters, Chatham, to Margaret Alice, second daughter of the Hon. Alfred Page, of Hobart, Tasmania.

Lowis—Mackay.—On May 29th, at St. Paul's Church, Mill Hill, London, N.W., Alfred Edmond Lowis, Chamberlain of Argyll, Inverary, to Harriett Sealy, younger daughter of the late F. R. MacDonald, M.D., Inverary.

MacWatters—Richards.—On May 1st, at St. John's Church, Peshawar, Cecil MacWatters, M.D., Indian Medical Service, to Nona, youngest daughter of the late Dr. George Richards, of Ross-on-Wye.

Death.

Biden.—On May 28th, at "Penrith," Wallington, Surrey, George Henry Biden, L.R.C.P.Lond., aged 41 years.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXIV. WEDNESDAY, JUNE 12, 1907. No. 24

NOTES AND COMMENTS.

Professor Koch and Sleeping Sickness.

PROFESSOR KOCH is the most unfortunate of scientists; he is always making discoveries which are no discoveries. No one in a position to form a reasonable opinion doubts Koch's genius, but the channels by which his discoveries reach the public ear are so uniformly fallacious—that is the kindest word to use of them— that one is almost forced to believe that like Eliza Hawkins he has only himself to blame. His latest fiasco is the atoxyl business. A few months ago the newspapers were trumpeting forth a cure for sleeping sickness discovered by Professor Koch. English research workers had been studying sleeping sickness for years without finding a cure, whereas Koch and his party sent by the German Government lighted on one in a few months. Thus again was the superiority of the Teutonic science demonstrated. Atoxyl, the "cure" in question, it was subsequently pointed out, is a preparation of arsenic which had been introduced to Koch's notice by English medical men in East Africa, who, with their colleagues in Uganda, had been using it experimentally in the treatment of sleeping sickness for a long time. The only difference between the Englishmen and the German was that whereas the former knew that though atoxyl could control the disease powerfully for a time, the effect was not permanent; yet the scientific German jumped to the conclusion that it was a specific cure. Last week Colonel Bruce, Director of the Royal Society Commission for the Investigation of Sleeping Sickness, wrote to the *Times* that there is at present no evidence that a single case of sleeping-sickness has been cured by anything, and Colonel Bruce is a man who can speak out of full knowledge. Although we have a high regard for the scientific ability of the German race, we have a far higher one for the accuracy of our own scientists, and we hope that the present lesson will help to keep Professor Koch's enthusiasm confined to the pursuit rather than to the publication of knowledge.

The "Medical Press" and the "Beacon Light."

LIKE Byron, we have awakened to find ourselves famous. The June number of the *Beacon Light* in its leading article deals with the subject of "Throat Troubles," and lo! a *quondam* editorial utterance of ours is quoted as an authority. To those on whom the *Beacon Light* has not shed its effulgence we may remark that it is the official organ of the British Anti-Tobacco and Anti-Narcotic League, and they will promptly gather the cause of the throat troubles in question. The editor has discovered that the ills and diseases of the throat are increasing in an "assuredly alarming" fashion, and at the risk of being stigmatised as biased, he believes this result is the outcome of the universal habit of smoking. "True," says he, "physicians' reports and obituary records do not state this, but it is not an uncommon thing in these days to ignore or hide the real cause of disease and death." We agree that it is not usual to state in the obituaries of physicians whether they smoked themselves to death or not, but we hardly fancy the fact would escape record did it occur. The MEDICAL PRESS AND CIRCULAR is invoked because of the innocent statement that excessive, and in some cases even the moderate use of tobacco affects the pharyngeal mucous membrane, and that it would be desirable to know under what exact circumstances this occurs.. Such is no doubt the fact, but we are faced with the extraordinary paradox that while the yearly sales of tobacco go up by leaps and bounds, the death-rate in England and Wales is steadily dropping. Perhaps the editor of the *Beacon Light* could get together a committee to study the causes of this puzzling phenomenon.

Crutches for Cripple Children.

IT is very difficult to say "No" to a Lord Mayor of London during his year of office, and Sir William Treloar is making use of his occupancy of the civic chair in a way that appeals to all kind-hearted people by endeavouring to raise a fund of £60,000 to provide for the cripple children—some seven thousand in number—of the metropolis. One of the devices he is employing for this purpose is the production of a book on the lines of the well-known *Printer's Pie*, containing pictures and stories by well-known people. This book appeared last week at the moderate price of one shilling, and the charitably, and even the uncharitably, inclined may be assured that the investment of that homely sum will bring its full return in material value. *Crutches to Help Cripple Children* contains a large number of really beautiful three-colour reproductions of pictures by well-known and talented artists, one alone of which—The Brooklet—is well worth the money. Besides, the pictures there are some capital black-and-whites, and some sixteen contributions in prose and verse by such writers as Mr. W. S. Gilbert, Max Pemberton, George R. Sims, William Le Queux, and George Manville Fenn. If we could stop at this point we should have nothing but complimentary things to say, but when we look on through the advertisements and see the Lord Mayor's appeal made the medium for bombastic self-laudation on the subject of deformities by such people as "Dr. Walford Bodie" and "Sandow," we think the limits of good taste—to put it mildly—have been far exceeded.

Cape Medical Libel. WE have to congratulate—and we do so very sincerely—Dr. Darley-Hartley, editor of the *South African Medical Record,* and Chairman of the Cape Medical Council, on having successfully sued a local newspaper proprietor and a newsagency for publishing a libel. It seems that a Dr. Crozier-Durham had been brought before the Medical Council charged with unprofessional conduct, and the libel complained of in the defendant's journal ran thus: "If it comes to advertising, there is no one more guilty of this than Dr. Darley-Hartley, and yet he has the effrontery to act as chairman of the Medical Council which sat on Dr. Crozier-Durham's case. But then Darley-Hartley does his advertising through skilfully engineered paragraphs in the local press, and he also uses politics as a medium for advertisement, just as some use church. Fancy a politico-medico of this type talking about observing the spirit as well as the letter. Why, he ought to be proceeded against." When the case came to trial, the defendant newspaper-proprietor put in the lamest excuse for the statement that press paragraphs were engineered, and, indeed, the whole defence fell through. The newsagency admitted the libel, and paid £5 into court as damages. The judge, however, raised their indemnity to £20, and assessed the damages against the other defendant at £30, costs going with the verdict. We cannot say that in our opinion the sums were adequate, but they were sufficiently substantial to mark the decided view of the Court, and completely to exonerate Dr. Darley-Hartley. In a comparatively new and markedly commercial community such as inhabits South Africa, it is highly important that the standard of medical conduct should be held high.

Movement Against Motherhood. IT has generally been assumed in the innumerable discussions about the falling birth-rate, that the policy of limiting families is one pursued by subterranean methods, and certainly its apologists have generally been half-hearted and apocryphal in their utterances compared with the full-blooded Malthusian days. However, it seems that the policy of passive resistance to procreation is to give way to one of active propaganda, in France, at all events, as in several towns—Lille, among the number—an anti-motherhood league has been formed, and the doctrine of limitation is being vigorously preached. Women are among the most prominent of the agitators, and special conferences are held once a month under the presidency of a well-known lady. The doctrine of the league is that large families are the work of illiterates, fools, and idiots, and that a well-filled quiver is a sign of ill-filled cranium. It must be rather amusing to see these orators, who are doubtless of the epicene suffragette type, lecturing married women on the sin of having children. But the grapes must be exceedingly sour before they could have brought themselves to it.

LEADING ARTICLES.

THE MEDICAL MAN AS CITIZEN.

IT is generally admitted that medical education has not yet reached the stage of perfection. Many suggestions have been made from time to time with a view of meeting real or imaginary defects in the scientific side of the matter. To ensure a happy professional life, however, some more practical guidance is required than that furnished by mere scientific ardour. The material interests of the medical practitioner, both individually and collectively, demand careful and intelligent protection. Should he aim at high scientific ideals alone, he is apt to find himself hopelessly handicapped in the daily struggle for existence. He apparently lacks the shrewd organising capacity of the lawyers, who, themselves under the protection of the most stringent trades-unionism in the world, are ever ready to condemn the propriety of medical fees, and the action of practitioners in the assertion of their pecuniary and ethical rights. No one blames the legal profession for having secured privileges by the ceaseless exercise of every possible extramural and intramural influence. On the other hand, everyone is inclined to laugh at the unpractical men of medicine, who grumble and agitate, but rarely achieve any real measure of reform either within or without their walls. One of the most encouraging advances of the past generation has been the foundation of the collective medical defence societies, whereby one part of the functions that should properly have devolved upon the General Medical Council has been admirably organised by the members of the medical profession. The reform of the Council, indeed, so as to render it an efficient representative and protective body armed with statutory powers, in our opinion, lies at the basis of the future welfare of the medical profession. At present the Council is little more than an anachronism. It constitutes an autocratic and non-representative body, in the main advisory as regards the Privy Council and Parliament. It is further armed with penal authority over duly qualified practitioners, which it administers with clumsy and, in many instances, contradictory procedure. But in the long run medical men must look to their own right hands for salvation. Recently they have shown signs of placing some effectual check upon unfair hospital competition. They will find it far more practical, however, in our opinion, if they exercise their vast power as citizens having the local and Parliamentary franchises. Reform of the Medical Acts is urgently needed, so as to give a governing body with extended powers on a representative basis. Consolidation of medical corporations into a one-portal system is a second much-needed measure. Stringent laws against irregular medical practice, again, would do more at a single stroke of the legislative pen to relieve the unfair competition against the medical profession than a century of internecine squabbling over ethical offences and jealousies, often of a trivial and technical nature. Then there is the vast question of the patent medicine trade, the suppression of which would not only release the public from a standing menace, but would also tend to bring the people back to sane and skilful medical treatment. There are many other directions in which medical men would be able to protect their own legitimate interests and at the same time to do incalculable service to the community. They might, to take one more instance, educate the public as to the desirability of a Royal Commission of Enquiry into the evils of the patent medicine trade. The most bitter opponents of progress and upholders of privilege could hardly venture to oppose so reasonable a request. In these and many other matters, then, we contend that medical men would do well to assert themselves as citizens. In the past it has been too much the fashion to regard the medical man as a being who should hold aloof from the busy doings of the world around him. The fruits of that policy are writ large in the increasing difficulties to which a harried profession has been reduced. If such a course were feasible, it would be of advantage to have some sort of education in medical economics, which should form part of the curriculum of every student of medicine. In that way he would learn from the first to regard himself as a factor of some importance in the development of his country. It is time that the prejudice which still lingers in many quarters against the participation of medical men in public affairs should be done away with. When the members of our learned but at present unpractical profession recognise more fully their private and national obligations, then there will be hope of a bettering of the general status and prosperity of an indispensable class of society.

TUBERCULOUS MEAT.

THE finding of the recent Royal Commission has convinced the sanitarians of the United Kingdom, at any rate, of the desirability of excluding the flesh and milk of tuberculous animals from human consumption. Hitherto, there has been no scientific protest against enforcing a precaution of the kind, so far as diseased flesh is concerned. Nor has there been any serious question with regard to milk, although it is true that in our own columns the absence of positive proof of infection by milk was pointed out by a gentleman whose views it is impossible to disregard. The objection, however, appears to be somewhat hypercritical, and it might be argued with almost equal subtlety as regards the origin of small-pox, mumps, and a number of other diseases that we know are communicable from the infected to the healthy. The truth appears to be that tubercle of the intestines is, in many cases, a primary infection, and, inasmuch as tuberculous cows may and do produce milk tainted with the tubercle bacillus, it follows that milk may in some instances be the vehicle of tubercular infection. That view appears to be accepted almost, if not quite, universally by medical officers of health throughout the country. Clearly, it is that of Dr. Mearns Fraser who is entrusted with the care of the sanitary welfare of Portsmouth. His views upon the risks arising from tuberculous meat are no less emphatic. In that belief he has recently issued a report that reveals an amazing picture of human selfishness and degradation. Briefly, he shows that an extensive trade is carried on in diseased animals, chiefly tuberculous cows, the market for which is mostly found in London. In one year, he states, no less than fifty-four cows were sold in Petersfield market for sums ranging from 10s. to 30s. each. During the same period seven cows were sold at Chichester at sums ranging from 5s. to 65s. each. The carcase which fetched 5s. as its market price appears to have been destined for consumption in Portsmouth, but on reaching that place the carcase was condemned and destroyed on account of tuberculosis. Dr. Fraser adverts to the well-known fact that cooking is no effectual safeguard as regards the destruction of the bacillus, and that raw meat-juice is often prescribed for children. In view of these considerations, not to mention the wider and more general probabilities involved in the systematic disposal of tuberculous flesh and milk, it becomes evident that stringent legislative interference is necessary in the interests of the community. The recent revelations as regards the American meat trade sent a thrill of horror throughout the civilised world. We have little hesitation in saying that they are hardly, if at all, less inhuman, revolting, and economically reckless of human life and happiness than the barbarous atrocities involved in the trade in diseased flesh that goes on within the four corners of the United Kingdom.

CURRENT TOPICS.

The King Edward Hospital Fund.

WE are pleased to state that an amendment of the King Edward Hospital Fund Bill has been framed, so far as the presidency of the Fund is concerned. The choice of any successor to the Prince of Wales is in future to be referred to a committee, consisting of the Prime Minister, the Lord Chancellor, and the Governor of the Bank of England, who will make their selection from the Royal Family. The status of the Council is also, we learn, somewhat changed, in accordance with earlier criticisms. It is to be hoped, however, that the Commons will not rest content until the desirability of a representative control of so important a public trust has been at least freely discussed in the House. There is no need to repeat our previous arguments in favour of a representative Council, especially in a small body that is not called upon to justify its decisions, no matter how arbitrary or unjust they may appear. We submit that in the present day the existence of a trust on the lines indicated is an anachronism likely at any time to lead to undesirable complications.

The Indian Government and Mr. Haffkine.

PROFESSOR RONALD ROSS, we are glad to note, is actively fighting for the reinstatement and adequate recognition of Mr. Haffkine by the Indian Government. As we have said more than once, Mr. Haffkine's treatment has been shabby in the extreme, and now that the full truth of the Mulkowal *contretemps* has come out, it is inexplicable that the grudge should be kept up. For every bit of evidence points to the contamination of the plague-prophylactic having taken place during the operation of injecting, and there seems no reasonable suspicion even that the contamination could have occurred in the laboratory. The bottle used was precisely the same as all the others; there was no cloudiness nor smell, such as there would have been if the tetanus-germs had been actively growing in it, and the incubation period in all the patients was long, as would not have been the case had a solution strong in toxins been injected. But even supposing the fault to have taken place in the laboratory, which no reasonable man would now admit, is Mr. Haffkine to be punished for the rest of his life because of a piece of carelessness on the part of an assistant for whom he was only nominally responsible? If every general whose subordinate made a mistake were politely dismissed from the Army, we should hear even more than now about the dearth of candidates for commissions. But considering what Mr. Haffkine has done and the enormous number of lives his prophylactic has saved, and considering that his magnificent discovery was freely given to the Government, it is shameful that his career and prospects should be ruined for an error which it now appears was due to the fumbling of a native assistant who was helping the medical man with the injections.

St. Maws and Consumptives.

IT is not often that a town objects to springing into favour as a health resort, but if we are to believe the statements we see, the inhabitants of St. Maws, in Cornwall, are stirred to indignation that their pretty village should be regarded as a suitable spot for consumptives. By way of choking off visitors with tuberculous tendencies, a circular letter has been drawn up and signed by the Rector, the Wesleyan Minister, a medical man, a matron, and several leading residents, warning the keepers of lodging-houses and inns of the danger they and their children run in receiving consumptives into their houses. The signatories say that there has recently been an increase in the number of visitors suffering from consumption, that when that disease has reached the expectoration stage it is a dangerous infectious disease, and that though they are sure the inhabitants would wish persons so afflicted to be treated with the greatest kindness and consideration in their own homes, they appeal to the community to keep them out of St. Maws. Now this action is one of a type which has been growing more and more common, and if the boycotting of consumptives is to become a recognised policy in every community, it is difficult to see what will become of these unfortunates. The degree of infectiveness of pulmonary tuberculosis is known with some degree of accuracy, and no properly-tended consumptive should be a source of danger to anybody, but it seems to be as necessary to start a campaign against overdoing precaution as it recently was to awaken people to the fact that consumption was infectious at all.

Immune Serums and the Opsonic Index.

AMONG our original communications in the present issue will be found one of much interest from Mr. Montgomerie Paton, of Melbourne. It deals with the passive raising of the opsonic index by immune serum administered by the mouth. Last year the same observer published some original papers in the MEDICAL PRESS AND CIRCULAR upon the use of serums in many pathological conditions. His results were of a striking and suggestive nature. In the present instance he has adduced the cases of a gentleman, subnormal to the staphylococcus, whose normal index of .84 was raised to 1.34 after the ingestion of one ounce of the author's anti-diphtheritic serum, and on another occasion from .72 to 1.78 after a similar dose. Should these observations stand the test of extended clinical experience they may possibly advance the science and art of serum-therapy by leaps and bounds.

The Presidential Address to the Irish Medical Association.

THE fact that Mr. McArdle was paid the unusual compliment of a unanimous election to a second year of office as President of the Irish Medical Association, may have been in part responsible for the optimistic spirit which permeated his Presidential address. He is satisfied with the Local Government Board, who "have done everything possible within the law in support of the just claims of our people." Does Mr. McArdle intend a sly hit at his predecessors for their involvement with this benevolent Board in the Drumcourath case, the costs of which have crippled the Association for years? Mr. McArdle is also satisfied with "the manner in which the public boards are now dealing with the rank and file of the profession." Has the President heard of New Ross, or of Irvinestown, to go no further back than the past few weeks in the history of the treatment of their medical officers by the public Boards of the country? The only things apparently with which the President is dissatisfied are the fact that the membership of the Irish Medical Association is not as great as it might be, and that the executive is occasionally subject to criticism. We entirely agree with Mr. McArdle, however, in his advice to the profession to hold together, and strive for their common objects. Without acquiescing in the view that the Local Government Board and the public boards throughout the country are all that they should be, we believe that the profession is its own chief enemy. The medical profession, being necessary to the community, is, if united, master of the situation; if divided against itself is reduced to servitude.

The Irish University Question.

The announcement of the Prime Minister in the House of Commons that the Government did not intend to introduce during the present Session a Bill dealing with the Irish University Question, withdraws from the arena of dispute a subject which has aroused great turmoil in Ireland. It is to be the task of the Chief Secretary in the autumn "to discover harmony among the jarring interests and views upon the subject in Ireland." Commenting on this suggestion, Mr. John Redmond, who, we think for the first time, expressed a half-hearted approval of Mr. Bryce's scheme, remarked that the task set the Chief Secretary was an impossible one. From Mr. Redmond's elegy on the dead scheme, it is clear, however, that whatever support it had got was only due to the fact that it had been put before the Irish public with the formula, "This or nothing." We are inclined, moreover, to think that Mr. Birrell's task need not be as difficult as Mr. Redmond anticipates. A perusal of the Report of the Robertson Commission, of that of the Dublin University Commission, and of the recent expressions of opinion called forth by Mr. Bryce's pronouncement, may lead him to find in the recommendations of the Robertson Commission a solution of the question which, if it does not receive universal approval, will, at least, escape the fierce opposition roused by Mr. Bryce's scheme.

A Quack's Agent.

The ramifications of the trade in illegal medical practice are no less manifold than remarkable. The story recently revealed in the Court of the Dewsbury Coroner, however, presents several features of much interest. It appears that a factory overlooker of the town mentioned was suffering from post-influenzal weakness, from which he was recovering under the care of a local medical man. Unfortunately, he fell into the clutches of a man named Hall, by whom he was persuaded to put himself under the treatment of a "Dr. Hall," of Manchester. The police evidence was to the effect that "Dr." Hall had no medical qualification. The case, therefore, becomes one in which the man Hall can be prosecuted under the Apothecaries Act, as he was stated to have sold medicine and to have assumed a medical title. That aspect of the case may, perhaps, be referred to the Medical Defence Union. There is also the extremely discomforting evidence that Hall had an agent at Dewsbury, who persuaded deceased to go to his principal. It appears that £2 10s. was paid for Hall's advice and medicine, and of that sum £1 10s. was handed to the agent as commission. In a matter of this kind it seems not unlikely that the law would regard both agent and principal as equally answerable for the offence indicated. In any case, the matter deserves careful attention in the interests of medical practitioners generally, not to mention those of the public, for in this particular instance the deceased appears to have succumbed to post-influenzal debility, a condition notoriously amenable to skilful medical treatment, although otherwise of a highly hazardous and fatal nature.

PERSONAL.

Mr. Holbrook Gaskell has added another to his numerous benefactions by contributing a further large donation (£5,000) to the building fund of the Liverpool Country Hospital for Children.

The fourth annual dinner of the Welsh medical profession was held at the Criterion Restaurant in London on the evening of May 31st, under the presidency of Sir Isambard Owen, M.D., F.R.C.P., Senior Deputy Chancellor of the University of Wales.

The annual meeting of the Royal Medical Benevolent Fund Society of Ireland was held on June 3rd in the College of Physicians, Dublin. The chair was occupied by the President of the Royal College of Physicians of Ireland.

Mr. David James Galloway, M.D., C.M. Edin., has been appointed an Unofficial Member of the Legislative Council of the Straits Settlements.

Mr. Arthur Greene, M.A., M.D., has been elected Assistant Surgeon to the Norfolk and Norwich Eye Hospital.

Mr. W. C. Stevenson, M.D., and Mr. W. S. Houghton, M.B., have been elected Surgeons to the Orthopædic Hospital, Dublin.

Dr. Robert J. Rowlette has been elected President of the Dublin University Biological Association for the Session 1907–8.

Principal MacAlister was entertained last week at a complimentary dinner at his old College of St. John's by the Regius Professor of Physic and the resident medical graduates of Cambridge in appreciation of his election to the headship of Glasgow University.

The will of Mr. Thomas Henry Wakley, F.R.C.S., editor and proprietor of the *Lancet*, whose death was recorded in these columns at the age of 86, a few weeks since, was "proved" last week under the sum of £35,607.

The will of Dr. Andrew Scott Myrtle, who died recently at his residence in Harrogate, at the age of 82, has been "proved" at £15,947. Dr. Myrtle was a J.P. for the West Riding of Yorks, and an esteemed contributor to this journal.

Mr. J. Dundon, F.R.C.S., and Mr. L. G. Gunn, F.R.C.S., have been elected additional Examiners in Surgery at the Royal College of Surgeons in Ireland.

Mr. J. Bland-Sutton, F.R.C.S., has kindly lent his house in London, at 47 Brook Street, for a *cafe chantant*, the proceeds of which are to be devoted for the funds of the Royal Eye Hospital, Southwark. A number of well-known artists have promised their services.

Dr. A. Wynter Blyth, after a service of thirty years as medical officer of health of the London parish of Marylebone, has resigned his appointment.

An important article on anti-typhoid inoculation appears in the May number of the journal of the Royal Army Medical Corps. It is written jointly by Brevet-Lieutenant-Colonel W. B. Leishman and Major W. S. Harrison.

A Clinical Lecture

ON

FOODS AND FEEDING IN CERTAIN CONDITIONS (a).

By SAMUEL WEST, M.D.Oxon., F.R.C.P.Lond.,

Physician to and Lecturer on the Principles and Practice of Medicine at St. Bartholomew's Hospital.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

Gentlemen,—Last week I spoke to you of foods. To-day I propose to speak of feeding. In some conditions, the kind of food given is an important—sometimes the most important—part of the treatment I propose to take a few of these; I cannot in such a lecture as this speak of all.

The first which I will take is that of newly-born infants. There can be no doubt that the best food for the newly-born baby is the mother's milk. However, sometimes mothers are ill, and I am afraid that, still more often, the attractions of society and the inconvenience of having to suckle a child every two or three hours causes mothers to be anxious to give up the nursing of their children. It then really becomes a question with which medical men have to deal, for one reason or another, in the course of their practice.

There are certain general principles of feeding infants, and the usual substance chosen is cows' milk. Recently I showed you that the dense curd which forms in cows' milk causes it to be difficult of digestion with babies or invalids, and I demonstrated to you how that, by the addition of a little citrate of potash to cows' milk, a grain or two to the ounce, the curd is rendered quite loose and therefore more suitable for infants' food. Another way that I explained of dealing with the milk, so as to make it more digestible, was by diluting it largely with either water or barley water, the proportions being one of milk to two of water; by partially digesting it, or by humanising it, *e.g.*, altering the amount of casein fat and sugar so as to approach the constitution of mother's milk But other kinds of food are very often chosen, as, for instance, some of the condensed milks. Swiss milk. though it contains too much sugar, is a food which children can live on fairly well.

But besides this kind of food there are two important principles to bear in mind in the feeding of babies. First, the amount which should be given at each meal; and, secondly, the frequency of the meals, *i.e.*, the intervals between them.

As regards the amount, you know that in the first days after confinement the breast of the mother has very little milk, and the child wants but little then; a few ounces of milk and water is sufficient. As the child grows, more food is required, and the meals have to be gradually increased in amount. The size of each meal and the total amount of milk required daily as the baby develops, all this I dealt with the other day.

As to the intervals, the general rule is that babies should be fed at first every two hours. In this connection you should bear in mind that all healthy babies vomit—that is to say, if they take a little more than their stomachs want they regurgitate it, and in that way it is disposed of. But if a baby really vomits a large portion of its food, it is evident that the food does not suit it. As the child grows the intervals between meals should become longer. Children three months old ought to be fed about every three hours, instead of two. There is no commoner mistake made by mothers, in feeding babies, than by giving the meals too often. When the child cries, the first thing done, either by the nurse or the mother, is to give it the bottle. In all probability the child is crying because it has got the stomach-ache, and if it gets more food at such a time it will cry all the harder, for it will have more pain. Whether the child cries or not, the same intervals should be rigidly observed, and with that in view you should have a diet chart with the diet written out that should be given every two or three hours. And it is quite as important in the case of the baby as in that of the adult, that you should have an efficient nurse where the services of such a person are needed. The so-called "experienced" children's nurse is an extremely conceited and lazy individual; she does not want to give herself any more trouble than she deems necessary. These "experienced" nurses are very risky people to deal with. Look with some suspicion on any person who calls herself an "experienced" nurse. Such people are experienced very often in evil ways, and, to get an undisturbed night's rest may give the child a sleeping draught or "soothing powder." There is a certain amount of worldly wisdom in the advice: If the baby does not thrive without any good reason, change the nurse.

Another fact about little babies is that they cannot digest starch. When they begin to cut their teeth they salivate copiously, but up to this time their saliva does not act properly on starch. For this reason, a child should not have starch in any form, however little the amount, until it is at least six months old. The best food to give babies is pure milk, or sterilised milk. If you have got your own cows, and know all about them, then you may give fresh milk. If, however, you have to deal with the kind of milk supplied in towns, and you do not know where it comes from, you have to be more careful and the milk should be sterilised. Either Pasteurise the milk at 150° F. for twenty minutes, or boil it. Of course, another very important thing is that all feeding-bottles and teats, by which the child is supplied with milk, should be kept perfectly clean. To this end they should always be well washed and kept in water that has been boiled. What led me to speak of sterilising the milk was, first, that a great deal of infantile diarrhœa and troubles of that kind which occur in childhood are really due to infected milk. In spite of all the precautions we take, we have even here in the hospital from time to time little epidemics which can be traced to milk. That being the case, how much more likely these epidemics are to happen where no such precautions are taken.

A great deal has been written lately as to the effects of giving sterilised food to babies. One statement, which is made on good authority, is that rickets is the result of feeding with sterilised or Pasteurised milk; but there are many authorities on the other side who do not accept this view. Personally, I do not think the evidence sufficient to justify so sweeping a conclusion.

Another condition which may arise from improper food is hæmorrhagic rickets, or, as it is called, scurvy rickets, or infantile scurvy. This is a very peculiar form of disease in children, not common, but very interesting, in which the limbs become greatly swollen and the swelling which is between the periosteum and the bone is largely due to extravasation of blood. No doubt, hæmorrhagic rickets is the result of errors in diet, just as ordinary rickets is. It will be recognised, therefore, that the feeding of little children is a very important matter. If a child be fed with improper food, it is starved, for it cannot digest that food. One reason why rickets is common among the poor is that they have improper foods, often starchy artificial foods, when they ought to have milk or some of its preparations. That is all I propose to say now about infants.

(a) Delivered at St. Bartholomew's Hospital, February 13th, 1907.

THE FEEDING OF FEVER PATIENTS.

I pass to another class, a very important group, namely, fever patients, and for the sake of being clear I will include for the moment any fever excepting typhoid. The best food for these patients is milk, or milk with egg beaten up and mixed together. An adult would require three pints of milk per diem, *i.e.*, five ounces every two hours or so, night and day, and to this might be added a couple of eggs beaten up. That is a very good diet for any fever patient. But supposing the milk does not suit, and, as a result the patient suffers from flatulence and vomiting, and passes undigested curds in his motions, greyish, flaky motions, with which we are familiar enough in children, though not so much in adults—the curd should be taken out, and an extremely good diet can be made of the whey and barley water, or the milk can be peptonised, or Benger's food should be given sometimes, and meat essences.

As regards the general question of beef-tea and meat essences. In fevers, if you look at the patient's tongue, you will find it coated; the mouth is dry, and there is defective secretion of saliva. The same thing holds in the stomach and intestines; there is a catarrhal condition of the mucous membrane, and, therefore, the digestion is impaired. The extracts of meat are very good in their way—beef-tea and such like—but they contain a very large amount of extractives, which are a sort of stimulant rather than food; they contain a large amount of nitrogen, and this must be got rid of by the kidneys. But the kidneys are in much the same condition as the digestive tract, and should not be given too much work to do. I am, therefore, against giving any large amount of these extracts in fevers. The patients are much better with barley water and milk. Beef-tea might be given once a day, perhaps, but not the concentrated essences. But, supposing you have a fever patient who cannot keep anything down, then you may find raw meat juice made in the cold a very useful thing. It is easily digested and readily absorbed, and very nutritious for its bulk. These patients will retain a fair amount of it in twenty-four hours, if given in teaspoonful doses; cooked essences they generally dislike, and the stock manufactured essences often disagree.

This brings me to another point. Should fever patients have water to drink? Certainly; and much good may result from it, because water helps the secretions of the skin and kidneys and bowels. They may have water slightly acidulated with phosphoric acid, but only a little at a time; or a little ice to suck, or a small piece of lemon. This will help to take away the thirst. Stick to your rules. Give the patients food every two hours, and if they are thirsty let them have water between, but nothing else. The old-fashioned imperial drink, composed of acid tartrate of potash, lemon and water, is an excellent fever drink, and acts as a diuretic as well.

A question to be considered, in all cases of fever, is whether the patients should get alcohol, and, if so how much? The great majority of young healthy people do not require alcohol at all, and in ordinary acute fevers, where there are no special symptoms, they are best without alcohol. In pneumonia, for instance, which, as we know, is a short, acute fever, a young patient gets on perfectly well without alcohol. But typhoid is a long fever, and the patient will very likely need some alcohol towards the end of it. The indications for giving alcohol are obtained from the pulse and the heart. A pulse of poor tone, little tension, and slightly irregular, especially if it be dicrotic, indicates the administration of alcohol. But a better indication still is the condition of the first sound of the heart. If the first sound of the heart be toneless, or if, as in some cases, it can hardly be heard at all, alcohol is clearly indicated.

What I have said, up to the present, will apply to typhoid fever, just as to any other fever. But there are one or two other points which I must add with reference to typhoid fever. It is sometimes extremely difficult to find a food which will suit typhoid patients at all. Half the diarrhœa which occurs in typhoid is due to defective feeding. The milky and curdy stools which used to be so common, and which are sometimes seen even now, were due to milk being given in quantities too large to be digested. In the present day, constipation is almost the rule in typhoid, and not diarrhœa. People talk about "a change of type" in the disease. It is not a change in type at all, but a change in method of treatment. As to the food to be given in typhoid, it is highly important that it should be suitable, and that the patient should stick to it. It is well in typhoid not to give meat essences, beef-tea, and such things. But what I want to point out is this: It is not so much the food, as change of food, that does harm. A typhoid patient, we will suppose, is beginning to get well, and his temperature is down, and the question arises, should he have a change of food? I should say that such patients ought to have no change of food until the temperature has never risen above normal for ten days. There can be no doubt, from clinical observation, that, for some reason or another, a change of diet in the early days of convalescence, in typhoid, does frequently result in relapse. I have, for instance, seen relapse occur from taking orange juice, egg, and other things. When working some years ago upon the excretion of urea, I was very much struck with the fact that in some cases the yolk of an egg, which does not contain much nitrogen, sent up the percentage of nitrogen in the urine from 1 to 3.5. It is just the same as in diabetic patients. A few grains of sugar given on one day may cause them to pass as many ounces of sugar, for some days, in consequence. Nearly all the relapses that come in typhoid fever come in the first week; some come in the second week, but it is quite unusual to get relapse after a fortnight, and, therefore, by carefully dieting of the patient for the first ten days of convalescence, the chances of food producing relapse are very small.

FEEDING IN NEURASTHENIA.

There is a disease called neurasthenia. It used to be called grave hysteria, though it is not, perhaps, hysterical at all. In some forms of insanity patients refuse their food and vomit everything they take. These cases are very closely allied to cases of neurasthenia. Neurasthenic patients can be temporarily cured by forced feeding. They will tell you that they vomit everything they take. But if they are put under close observation and fed, and, when they refuse their food, are forcibly fed with a nasal tube, a large number of them will retain the food given them, even when in large amount. If feeding be supplemented by massage, the nutrition is still further improved. Most of these cases go on very well up to a certain point, but many relapse subsequently.

FEEDING IN PHTHISIS.

A great deal is written just now about the sanatorium treatment of phthisis. Part of this consists in over-feeding, or excessive feeding. But it is no use putting food into the stomach unless it goes farther and gets out of the stomach into the blood vessels and lymphatics. It was quite ridiculous to prescribe for these patients a large diet which they could not or did not retain, but vomited almost at once. Excessive feeding, irrational stuffing, is being largely given up now in sanatorium treatment, and wisely. Such patients should, of course, be fed well, but it is no earthly good upsetting their digestion and comfort in the way described.

FEEDING IN GASTRIC ULCER.

Take another class of case—gastric ulcer. Students as they go round the wards do not seem to value much these questions of diet and treatment. Yet one of the first questions when you get into practice may well be how you are to manage a case of gastric ulcer, what diet you are to put it on, and how you are to manage it afterwards. Let us suppose a typical case: A young woman has got a good deal of pain just after anything has been taken into the stomach. She vomits frequently and, occasionally, vomits blood.

It is no good putting into the stomach food which is going to be vomited, and which causes pain, and might bring on hæmorrhage. Therefore, the first thing to do with such patients is to stop everything by the mouth and feed them by nutrient enemata. In the first place, the bowel must be washed out once or twice a day with water to keep it clean. Then, every four hours, a nutrient enema should be injected slowly; otherwise it will not be retained. Patients may live on nutrient enemata for many weeks. But we do not, as a rule, find it necessary to employ that method of feeding for more than two or, perhaps, three weeks in ordinary cases. At the end of that time all the symptoms in the stomach may have vanished, and you may be able to feed the patient by the mouth again. You would begin with small amounts of food, like barley water or whey, which is nutritious and leaves no residue. That would be gradually increased in amount. Next you would give a little peptonised milk, and then a little pure milk, in small quantities. Give one or two meals of this kind a day to begin with. Let the nutrient enemata be gradually discontinued as the patient is able to take more by the mouth. Then, perhaps, a little Benger's food may be given, or a little custard, or a lightly boiled egg then some pounded meat or pounded fish, and then solid food, fish, or fowl, and so on.

Feeding in Diabetes.

In Mellitus Diabetes diet is by far the most important line of treatment. It is necessary to eliminate from the food so far as possible all things likely to increase the production of sugar, *i.e.*, sugar itself and starchy substances. In this disease of such long duration as it is, the problems of diet will tax all the skill and resources of the physician.

Feeding in Scurvy.

Scurvy is a disease of which defective diet is the cause, and which can be cured by proper food. It is produced by the want of vegetable or vegetable acids, and cured by their addition to the diet. In this way this disease has been practically banished from our Navy, though it used to incapacitate whole ships' crews. We occasionally meet with scurvy in the middle of London, although we are not far from Covent Garden and other vegetable markets.

Feeding in Renal Diseases.

Another condition to which I may refer is renal disease, and, in connection with this, diet is of great importance. Why? Because the kidney is the only organ by which nitrogenous substances, after they get into the body, can be eliminated. Therefore, we must not in the food increase the amount of nitrogen. The nitrogen in the urine has two sources—the food, and the decomposition of the tissues. You cannot reduce very much the natural exchange of substances in the tissues. Metabolism may be increased, or decreased, to some extent, but that we cannot effect much by diet. But we can reduce very considerably the amount of nitrogenous substance in the food. Albuminuria in renal disease is not an indication for treatment. You hear it said: "This patient has got albumen in his urine, and therefore he has had this or that diet." But there may be albumen in the urine, and yet the kidneys may have nothing the matter with them. The albumen is a very common indication of something being wrong with the kidney, but it is not itself a thing that requires treatment. If you come to the conclusion that a patient's kidneys are not sound, consider the diet of that patient. In acute renal disease the less nitrogen given the better, because the whole kidney is in a condition of acute inflammation, and is able to do very little work, and when anything more than the minimum of nitrogen necessary is given the work of the kidney is increased. There is something more to be borne in mind about kidney disease. If a patient is going to get well of kidney disease, how is that going to be? The cells of the kidney have undergone a peculiar degeneration and a great many of them have been shed; they may be seen in the casts. The kidney will not get well until it grows new cells, and if it is to grow new cells these cells must be properly fed; otherwise the cells will not be healthy and sound. As a matter of fact that is a daily experience in renal disease. If a patient with acute renal disease is placed on milk diet, he may improve up to a certain point, but the time comes when he will get no better upon milk alone. Then the diet is changed and immediately renewed improvement follows.

Let me take another group of renal disease—granular kidney, chronic interstitial nephritis. These patients are going to be ill a long time. They have got a disease which cannot be absolutely cured, although much may be done for its relief. In chronic nephritis the mischief is done before the patient comes under observation. Then very often there is only a slight trace of albumen in the urine, and yet the albumen is made the test of the treatment, and the patients are put upon strict diet and they begin to flag. A large number of these patients are best treated by giving them the minimum of nitrogen that they can digest. Treat them on common-sense principles, and they will improve very much.

The great thing to avoid in all renal disease is such food as meat extracts and meat juices. These extracts of meat contain all the extractives you can get, and sometimes very little of the nutritious part of the food. A little piece of fresh meat would be very much better than most of those extracts of meat.

Feeding in Skin Diseases.

Skin affections form another group of cases in which diet plays an important part. Acne is a very common skin disease, which you often have to treat, and it is affected largely by diet. Acne is no doubt a germ disease. Diet, I suppose, must act by altering in some way the chemistry of the tissues so that the skin offers less resistance to the ubiquitous germ.

Another skin disease in which diet forms an important part is eczema. There are two lines of treatment of eczema—the local treatment, varying with the particular form of the affection, acute or chronic; the general treatment, depending on the patient's general health; and in this diet is of great importance, especially in babies. There are many babies who have eczema simply because they are improperly fed. I remember seeing a baby covered with eczema, though otherwise quite a healthy-looking little child. I asked the mother, "What ought a baby six weeks old to be fed upon under ordinary circumstances?" She said, "I do not know what you mean," and then it suddenly dawned upon her that it should be fed upon the breast only. "Now go away," I said, "and feed it upon the breast-milk only, and nothing else." I never saw that child again, but I heard that in a week's time it was well.

There are, of course, a great many other things that I might have mentioned in relation to diet in disease, but I have only had time to-day to indicate in some special diseases some of the general principles which should guide you in treatment.

Note.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by Peter Horrocks, M.D.,Lond., F.R.C.P., Senior Obstetric Physician, Guy's Hospital; Lecturer on Obstetrics and Diseases of Women in Guy's Hospital Medical School, etc. Subject: "Disorders of Micturition in Women." (Two lectures delivered at Guy's Hospital).*

Dr. George William Armstrong, of Treorky, was summoned at Newport on June 3rd for driving a motor-car (DW 144) in a manner which was dangerous to the public in Bridge-street and Commercial-street on Sunday afternoon, May 26th. Mr. Abbott (from the town clerk's office) appeared for the prosecution: Mr. L. H. Hornby defended. The bench imposed a fine of £3 and costs.

ORIGINAL PAPERS.

REPORT OF TWO SUCCESSFUL CASES OF CÆSARIAN SECTION, WITH OBSERVATIONS.

By C. YELVERTON PEARSON, M.D., F.R.C.S.
Professor of Surgery, Queen's College, Cork; Surgeon to the County and City of Cork Victoria Hospital for Women and Children, &c.

Cæsarian Section is an operation which up to the present time has very rarely been performed in Munster. Apart from this fact, to which I shall again allude, and the general interest of the subject, the cases which I am about to report present some features of special interest, which induces me to bring them under the notice of this section of the Academy.

Case I. *Radical Cæsarian operation for obstruction due to large pelvic fibro-myoma.*—Mrs. "M. D." æt. 35 years, farmer's wife, recommended by Dr. Reid, of Bandon, consulted me on February 23rd, 1906.

She was a woman of rather sallow and somewhat anæmic appearance, but had always been healthy up to date of marriage, which took place on July 29th, 1905. Menstruation, which had previously been regular, had ceased after marriage. According to her first account there had been no menstrual period since the early part of July, but she subsequently stated that she was unwell about a week after marriage.

Two months ago she noticed a swelling in the hypogastrium to the right of the middle line; about a month after she suffered from intermittent pain of a darting character in the same situation, which had become more constant for the past ten days, and for which she consulted Dr. Reid, who, on examination, found a large tumour in the pelvis, but was unable to detect any sounds of the fœtal heart. There had not been any sickness, and the woman had no suspicion of pregnancy.

On examination.—The breasts were found to contain milk, and presented all the characters associated with a first pregnancy. The abdomen was considerably enlarged, and on palpation a small, hard tumour about the size of a hen's egg was felt in the right iliac region, a few inches above Poupart's ligament. There was a sensation of marked resistance in the hypogastric region produced by a tumour, and a general fulness was detected, dull on percussion, extending two inches above the umbilicus, which corresponded in feel with what might have been a pregnant uterus.

On vaginal palpation a large, apparently solid tumour was felt through the anterior vaginal wall, which, though very fixed, could also be felt by the hand placed above the pubis. The cervix was lying behind the tumour, and was so high up that it could be reached with difficulty. On auscultation, though a soft systolic souffle was heard over the hypogastrium, no sounds of the fœtal heart were perceptible. The patient had not experienced any distinct sensation of quickening.

A problematical diagnosis of pregnancy, associated with pelvic fibro-myoma, was arrived at, which was confirmed on further observation of the patient while in hospital. She was sent home on March 3rd with instructions to return during the first week of May.

Shortly after her return home the patient experienced distinct sensations of quickening, and when visited a few weeks afterwards by Dr. Reid, he was able to hear the fœtal heart sounds distinctly.

The patient returned on May 7th, and was re-admitted to the North Infirmary. There had been no change in her general appearance save those produced by the more advanced condition of gestation. The pelvis was so completely blocked by the presence of a large fibroid tumour that it was with extreme difficulty the os uteri could be reached, lying behind the tumour and high up in the hollow of the sacrum. It was evident that delivery could not be accomplished in the natural way. So far as I could calculate from the woman's statements the onset of labour would be likely to occur during the second week of May. I determined to anticipate this by operation, and made all the necessary arrangements.

On careful palpation of the abdomen the position of the fœtus was found to be as follows:—The body was placed obliquely, the dorsal aspect to the front, and the head being placed upwards and to the right of the fundus. The position of the placenta could not be determined by palpation, but was believed to be posterior. The fœtal heart sounds were quite distinct and best marked to the right of the umbilicus.

All arrangements were made for operation, which was performed on Saturday, May 12th, in the presence of the other members of the staff and several medical friends. I was assisted by my colleague, Dr. Henry Hobart, the anæsthetic was administered by Dr. Hegarty, whilst Dr. Richard Byrne stood ready to receive the child. The operation presented no feature of difficulty. The abdomen was laid open by a five inch incision, the parieties were pressed backwards, the uterine walls were incised till the membranes were exposed, and the incision was then increased to about four and a half inches in length in an upward direction with scissors, the membranes having been divided the child was seized by the neck and extracted without difficulty, the head being delivered first. The cord was divided between two pairs of compression forceps, and the child, a well developed boy, was handed over to Doctor Byrne.

The uterus was then seized and drawn forwards through the abdominal wound, and immediately began to contract. On making firm traction on the uterus in an upward and forward direction the large pelvic tumour was drawn out of the pelvis. The remainder of the operation was completed as an ordinary supra-vaginal hysterectomy, silk ligatures being applied, the stump and peritoneum over it being sutured with iodised catgut.

The bleeding, which was very free during the division of the uterus, practically ceased after delivery of the child, and gave no further trouble. The placenta was left *in situ*, but very soon became separated by the contractions of the uterus. The ovaries were not removed.

The woman and her child progressed in a most satisfactory way, and both left the hospital on June 9th.

Case II. *Ordinary Cæsarian section for spondylolisthesis and contracted pelvis.*—Mrs. "S. D." æt. 33 years, consulted me on December 27th, 1906, by the advice of Doctor O'Meara, of Skibbereen, who had previously written to me about her, and expressed the opinion that he regarded it as a suitable case for Cæsarian section.

The patient was of healthy aspect and of small proportions, though well formed. Judging by her appearance at the time, I should have thought that her height did not exceed 4 ft. 6 in., though when she was measured some weeks after operation her height was found to be 4 ft. 9 in. She had marked lordosis, and the abdomen was unusually prominent even for advanced pregnancy.

History.—She was married 4½ years, and had no living children, though she had three confinements. Delivery at the first was accomplished by turning followed by craniotomy. At the second she was delivered with great difficulty by forceps of a dead fœtus, but the exact period of gestation was not known. On the third occasion she was delivered naturally at about 6½ months, and the child was said to have lived a few hours. This was in April, 1905. It appeared from her statements that she had now reached full term, and that labour might come on at any moment, though she had been advised to come to me at an earlier date. I advised her to immediately go into hospital, but it appeared that she had no intention of submitting to any severe operation, and wanted me to undertake the delivery *per vias naturales*, which I firmly declined to do. She wanted to return home immediately, but finally consented to go into hospital and think over the matter till the following day. She left my house on the understanding that she would go into hospital, but on getting there changed her mind and determined to stay somewhere in the City for that night. About 11 p.m. her husband presented himself at the hospital saying that she was in labour, and asking to have her admitted. I was communicated with by telephone, gave instructions for her admission, and ordered a bromidia draught and quarter grain of morphine hypodermically, with the understanding that I would be summoned if labour continued. The pains ceased soon after her admission, and she passed a good night. On the next day preparations were made for operation, but I determined not to operate until the day following unless obliged to do so, in order that more methodical preparatory treatment could be carried out. On examination *per vaginam* the pelvis was found to be small and imperfectly developed, but no systematic measurements were made either then or subsequently.

Cæsarian section was performed at 10 a.m. on December 29th, in which I was assisted by my colleague, Dr. Hobart, the anæsthetic (C.E. mixture) being administered by Dr. Michael Cagney. In less than five minutes from the commencement of the operation a healthy male child was extracted, which at once cried lustily, and weighed 6½ lbs.

The placenta was partially divided before the membranes were reached, owing to its occupying an anterior position, and though the bleeding was free at the moment it practically ceased when the child, which lay in the left occipito-anterior position, was extracted. The moment this was accomplished the uterus spontaneously delivered itself through the abdominal wound. This was easily explained by the prominence of the lower lumber vertibræ, which were now found to be on a level with the anterior abdominal wall. As the uterus did not contract very rapidly the placenta and membranes were separated and extracted. The uterus did not even then seem disposed to contract satisfactorily, and as the patient seemed at the moment to suffer from shock, I douched both the exterior and interior of the uterus with hot saline solution, to which it at once responded in such a marked manner that it became quite anæmic in appearance. The uterine wound was closed by two rows of continuous suture of iodised catgut, and the abdominal wound was sutured in three successive layers.

The case pursued an uneventful course, the subcuticular suture was removed on the fourteenth day after operation, and both mother and child left hospital on January 19th, 1907, twenty-one days after operation.

Observations.—The special points of interest in the preceding cases have already been sufficiently alluded to. It will be noticed that in both cases, acting on the experience of Dr. Howard Kelly, I appointed a particular time for operation, and did not wait for the onset of labour, though in the second case I was very nearly anticipated. From the experience gained in these cases I would follow a similar course if possible in future cases.

Further, I think it is unnecessary to stop during the course of the operation, previous to the extraction of the fœtus, to arrest any uterine or placental bleeding. Firm pressure of the assistant's hands placed on the abdominal wall on either side of the wound will sufficiently control it. After extraction of the child it does not appear that there is much danger of hæmorrhage, as if the uterus does not take on action immediately it can be stimulated by extracting the placenta and hot douching.

I should like to advise all those practitioners who meet with cases which are likely to require surgical assistance to see that the patient is placed in suitable surroundings and all necessary arrangements are made for operation before the onset of labour, even though it may be thought wiser not to operate till the pains have commenced.

The great rarity of Cæsarian section in the South of Ireland can be easily explained on the following grounds, viz. :—(1) Cases of pelvic deformity of such a degree as to necessitate such an operation are comparatively few. (2) In the majority of cases of difficult labour among the poorer classes the medical attendant does not get an opportunity of recommending such an operation, as his services are not sought for at a sufficiently early period. I have no doubt with the improved education which midwives receive, and an increased confidence in surgical measures, the number of such operations in the future will increase.

NOTES ON THE PASSIVE RAISING OF THE OPSONIC INDEX BY IMMUNE SERUMS.

By D. MONTGOMERIE PATON, M.R.C.S.Eng., L.R.C.P.Lond.,

Of Melbourne.

Since the publication of my work on the "New Serum Therapy" (*a*), which advocated the oral use of serums, both normal and the product of acquired immunity, for various diseases, the writer has continued his work and can only confirm the results already stated. "Tissue resistance" was given as the cause of the effects

---

(*a*) "The New Serum Therapy," pp. 320. Price 6s. Lond. Bailliere Tindall and Cox. 1906.

produced by the serums used. The conclusions arrived at were that this resistance was a constant factor in immunity, whether natural or acquired, that it might be present along with antitoxins and bacteriolysms (and might be the whole resistance itself), and yet was distinct from either of them; that it rendered the soil insusceptible to the action of the organisms present, so that the patient's functions were restored to normal even while the organisms were present. For these and other clinical reasons, such as the action of normal horse or sheep plasmata in tubercle in which infection the results obtained were identical with those of Professor Wright by his tuberculin treatment, both as regards the class of cases benefited and the benefits obtained, the idea presented itself that the oral use of the serums must cause the production of some sort of opsonins. To test this, the following experiments were made by Dr. Julian Smith, of Melbourne, a recent pupil of Professor Wright. The writer is subnormal in his resistance to the staphylococcus, and became the subject himself. The experiments were carried out under the strictest rules :—

Results.—Normal index, October 7th, 1906, ·84; normal index, October 10th, 1906, ·93. After ingestion of 1 oz. of "Paton's" Anti-diphtheritic Serum (P. D. & Co.) during previous eighteen hours, October 14th, 1906, 1·34. No further serum taken and normal index was again taken, October 25th, 1906, ·72. One ounce same serum during previous eighteen hours, serum heated to 60° C. before use, October 29th, 1906, 1·78.

The heating of the serum was done so as to preclude the possibility of the presence of opsonins. The age of the serum and the antiseptics in it were practically sufficient to do this without the heating.

Thus the result obtained showed that no opsonins being present in the serum, there must have been some reaction which produced them. In any case the opsonic index was passively and immediately raised by the oral use of the serum employed. Now the serum employed was the product of the direct attack by a toxin on the tissues and the organisms producing the toxin had nothing else to do with the production of the immunity. Hence the serum contained the elements necessary to protect the tissues from the toxin, and they were thus the product of a tissue reaction. But the product of a tissue reaction caused the production of opsonins in the patient as it was intended to do in the animal supplying the serum. The conclusion therefore is that the serum produces a tissue reaction which in turn produces an opsonin and the two combined form the "tissue resistance" which has been described in "New Serum Therapy." Thus the action of the serum described as causing a recuperative effect on the involuntary muscle is a tissue reaction, and the action on staphylococcic infection is due to the reaction plus the opsonin.

Natural immunity in the sheep and horse to tubercle is the same in character as in the human, but in efficiency it is much greater. If the elements producing opsonins are transferred by the oral use of the serum, then the normal serums of these animals should be beneficial in tubercle. This is so, and the results are the same as those in patients under Wright's tuberculin treatment.

The reaction alone is required in cases of debility and lowered nutrition arising from nonmicrobic causes. Abnormal lactation from such causes is specifically rendered normal by the oral use of the normal plasmata. The passive raising of the opsonic index and the maintenance of the tissue reaction demand the use of the serums till they are no longer required.

The object of antitoxin is to neutralise toxin, and this is done like any other chemical reaction, but the object of the tissue resistance is to maintain the tissue integrity and function and hence it has to be maintained till the attack upon them has ceased and the infection eliminated.

They can be given in any stage of a disease, as there is no negative phase following their exhibition, but naturally the earlier the better.

We know the value of Professor Wright's methods, limited as is their scope, to prevention and local infections, but what must be the value of a method which can raise the specific resistance of the patient after the onset of disease and in any stage of it thereafter?

This is a principle which has acted all through with me, not only in anti-diphtheritic serum, but also in anti-streptococcic serum, and in the normal plasmata of the horse and sheep to tubercle.

Reading "New Serum Therapy" in the light of the above will give thoughtful men much fruitful suggestion.

NOTES AND COMMENTS ON A CASE OF LATE RICKETS.

By J. A. COUTTS, M.B.Cantab., F.R.C.P.Lond.,
Physician to the East London Hospital for Children.

The estimation of the frequency of occurrence of "late rickets" varies largely with the conception of the individual observer as to what constitutes that complaint. With those authorities who claim that the complaint may be limited to a single bone, and who ascribe coxa vara, scoliosis, and many other deformities to a late rachitic condition of the affected bones, "late rickets" is far from a novelty. But to those of us who restrict the term "late rickets" to a complaint in which the whole of the osseous system is affected in a manner closely resembling that occurring in the infantile disorder, cases of "late rickets" are extremely rare. In a long experience at a children's hospital, I have only met two examples of the complaint in my personal practice, but owing to the kindness of Mr. Muirhead Little, I have had the opportunity of examining three or four more at the National Orthopædic Hospital. From what I gather, indeed, the complaint would seem to be more frequent at orthopædic than at children's hospitals, and often, too, the chief manifestations of the disorder occur at an age beyond that of the patients seen at the latter institutions.

Not very infrequently the osseous changes produced by an infantile rickets are unduly prolonged, and are still demonstrable in the sixth or seventh, or even later, years. Such cases must be clearly differentiated from those of true "late rickets," where the osseous changes do not start until the age of infancy is past. The age of onset in accepted cases varies widely, in some being as early as the fourth, and in others as late as the seventeenth year. It is noteworthy that in a large majority the onset has been preceded by some prolonged and debilitating complaint, such as a chronic diarrhœa, and in some by a definite and protracted colitis.

My second case was one of some half-a-dozen others that were shown at the first meeting of the present session of the Clinical Society to illustrate Mr. Clutton's Presidential Address on "late rickets." The appended notes of her condition are brief, as the chief interest in the case lay not in the bony manifestations themselves, but in the time of their onset.

I—H., a girl, æt. 7, was admitted into the East London Children's Hospital on October 3rd, under my care. She was one of a family of seven children, of whom one suffered severely from rickets in infancy, whilst the other six, including the patient, had escaped the disorder at that period. The patient, as far as the mother could recollect, had been suckled for three or four months, and after that bottle-fed. She was early in teething and talking, but did not walk until about 18 months old. Once acquired, her walking had been perfectly normal until the onset of her present complaint. She had been considered "delicate," but had no definite illness until 4½ years old, when she had a severe attack of measles. Since the measles the bowels have been irregular, diarrhœa alternating with constipation. Shortly before five years old it was noticed that her ankles, knees, and wrists were growing big, and the enlargements have increased until the present time. During the past year her walking, which had formerly been good, had become more and more defective, and this, together with a supposed decrease in height, had been the main cause of her being brought to hospital.

On admission she was a pale, red-haired child of short stature (height 3 ft. 1¾ ins.), but looked bright and intelligent, in spite of the loss of most of her temporary teeth. The most striking feature in her case was the extreme epiphyseal enlargements of the ends of the long bones entering into the formation of the ankle, knee, and wrist-joints. One noticeable point was the amount of enlargement of the upper epiphyses of the tibiæ and fibulæ, the enlargement being greater than that usually seen in the same parts in infantile rickets. The same feature was seemingly constant in the other cases shown at the Clinical Society's meeting, and was commented on by several observers. In addition to the enlargement of the epiphyseal ends, the femora were distorted, having one bend with the convexity anterior, and another with the convexity outwards. Both tibiæ and fibulæ were bent to the same degree and in the same directions as the femora. The gait of the child was somewhat "waddling." Her frontal and parietal eminencies were somewhat excessive, but the skull was not flattened on the vertex, nor was any vestige traceable of the former situation of the anterior fontanelle. There was marked beading of the ribs, but no other deformity of the chest. The liver and spleen were not enlarged, and beyond that in the osseous system there was no evidence of constitutional disturbance. A volumetric analysis of the urine showed that the phosphates were markedly increased, being nearly double the normal amount for a child of her age.

The close resemblance of the bony changes in such cases to those occurring in infantile rickets is not to be gainsaid. We have it, too, on high authority, that both the macroscopical and microscopical changes in the epiphyseal cartilages are undistinguishable from those occurring in the same parts in infantile rickets. But whether the two complaints are identical may be open to question. Contrasting "late" with infantile rickets, in the older patients the disease is much more persistent, lasting usually for many years; there is an absence of constitutional disturbances, the shafts of the affected bones become much softer, and in later stages multiple osteotomies are much more often called for at the hands of the surgeons.

In a large proportion of cases of "late rickets" there is a history of the patient having suffered and recovered from rickets in infancy. The frequency of this association has led many observers to assert that every case of "late rickets" is a recrudescence of an infantile rickets that has been recovered from, and the name "recrudescent rickets" is sometimes used in preference to the one more commonly employed, to prove a negative is as impossible as it is to guarantee the absolute freedom of an older person from having suffered from some degree of rickets in infancy. But in many cases of "late rickets" there is no history of rickets in infancy obtainable, and this was so in three out of five cases of which I have personal knowledge. On these grounds I prefer the more commonly accepted term "late rickets" to that of "recrudescent rickets," and agree with Mr. Clutton that rickets may have its primary onset at periods of life far beyond the infantile age.

THE OUT-PATIENTS' ROOM.

ROYAL FREE HOSPITAL.

Charcot's Disease of the Knee Joint.

J. P. Legg, M.S., F.R.C.S.

A man, æt. 35, came to the Out-Patients' Room complaining of a swelling of the right knee which had come on suddenly three weeks previously. There had been practically no pain, and he was able to walk quite well.

On examination the joint was found to be very much swollen, the swelling being due to a large quantity of fluid. Fluctuation was readily obtained, and the synovial membrane did not appear to be particularly thickened. On the inner side of the joint the skin was reddened and œdematous, this was partially due, no doubt, to the patient having rubbed in turpentine vigourously. The movements of the joint were not at all impaired, flexion and extension could be carried out to the full amount; in addition, a very great degree of lateral movement was obtained. All the movements were painless, and much coarse grating was felt on carrying them out. The popliteal space was occupied by a globular fluid swelling on the inner side, and behind this the upper end of the tibia, or the lower end of the femur was easily made out to be displaced backwards. It was quite easy to push the bones forward, and when they were allowed to slip back again a coarse grating was detected. Around the upper end of the tibia, a number of bony or cartilaginous nodules were present, especially on the inner aspect of the bone. The inner articular facet of the tibia appeared to be hollowed out into a cup-shaped depression. The lower end of the shaft of the femur was thickened by a uniform bony mass all round the circumference, and the patella was about half as big again as that of the opposite side. When he walked the only things noticeable were the limping, and the fact that the whole limb was bowed outwards, the knee being the maximum point of the curve. All the other joints were apparently healthy. Mr. Legg pointed out that in this man all the characters of Charcot's disease of the joint were present; the patient had also an interesting past history. Two years ago he was in the hospital with cellulitis of the left foot, and a perforating ulcer of the right foot on the ball of the big toe. On investigation, he was found to have no knee jerks, to have lightning pains, and unequal pupils, the right being the smaller; both pupils reacted to accommodation and to light—to the latter sluggishly. The cellulitis got well, and he left the hospital. A few weeks later he came back again, and said that whilst going upstairs the right thigh bone suddenly snapped. The whole thigh at the time was distended and tense from a large effusion of blood; and there was a fracture in the lower third of the femur. He was treated by the means of a long Liston's splint and weight extension. A large mass of callus formed. The fracture eventually united firmly, and has caused him no trouble except from the shortening, which has resulted in a limp. Up to the present time the signs of tabes have not advanced; he has unequal pupils which still react sluggishly to light; there are the lightning pains and the knee jerks are absent. When he walks there is no ataxia, and it was interesting to notice, Mr. Legg thought, how well a patient with such a joint condition was able to get about.

This patient then, Mr. Legg said, showed three of the most important complications of tabes, and all occurring in the apparently early stages of the affection, whilst at the same time the primary disease does not seem to have advanced during the last two years. It was usual for these conditions to occur whilst the signs of tabes were not very evident or not noticed by the patient; in fact, the affection of a joint, the spontaneous fracture of a bone, or the perforating ulcer might be the reason for the patient seeking advice, and it was only on careful examination that the early evidences of the tabes were discovered. As to the diagnosis of Charcot's disease of the joints, the most important points were the rapid onset and rapidity with which the joint is destroyed. Every structure in the joint is involved, the ligaments being singled out quite early. In this man, the capsular ligament was rapidly expanded, and the marked lateral mobility, which was a very characteristic sign, together with the displacement backwards into the popliteal space of the ends of the bones, could only be the result of destruction of the lateral and crucial ligaments. Whilst this destruction was going on, new bone was being deposited in the capsule, and around the margins of the joint surfaces, as was shown by the nodules which could be felt and the enlargement of the patella. Painlessness was another characteristic, though some patients complained of "rheumatism" in the joint, and very often of the lightning pains.

The elastic swelling in the popliteal space was probably one of the bursæ distended with fluid. It was not uncommon to find such bursal swellings in connection with Charcot's disease, and the bursa here involved was that which frequently communicates with the joint, namely, that under the semi-membranosus muscle. Possibly this swelling might be the back part of the joint capsule bulging into this region owing to the weakness of the posterior ligament of the joint, but the characters of the swelling were more like those of a distended bursa.

Now as to treatment, something, Mr. Legg affirmed, could be done. (1) By means of a moulded leather splint embracing the leg and the thigh. The great thing, he considered, was to limit the lateral mobility, which could be done by metal supports on each side. Sometimes these might be hinged to allow flexion and extension. (2) If the joint continued to be increasingly distended, or if the amount of fluid was very great, aspiration of the fluid was useful; he mentioned too that the amount of fluid varied from time to time.

A skiagram taken the same afternoon showed extensive alteration in the shapes of the joint surfaces; a large mass of callus around the site of the fracture of the femur, the lower fragment being twisted and displaced backwards, and nodules of bone attached to the upper end of the tibia and in the capsule away from the bone.

OPERATING THEATRES.

GREAT NORTHERN HOSPITAL.

Rupture of the Lateral Sinus.—Mr. Arthur Edmunds operated on a man, æt. about 40, who had been admitted to the hospital suffering from an injury to the skull. The history of the case was that the patient had fallen, striking his head over the left side of the occipital region. At the time of his admission, four days before the operation, his symptoms were slight and equivocal; he was conscious, had no paralysis; indeed, the only sign of cranial injury was pharyngeal hæmorrhage; there was no hæmorrhage from the ear. After he had been in the hospital, however, for three days, he began to exhibit a slight degree of facial paralysis and a squint. On the day of the operation the facial paralysis was complete on the left side, and careful examination of the ocular movements demonstrated a complete paralysis of the left external rectus; apparently the other ocular muscles were intact. The patient was conscious, answered questions rationally, but was if anything a trifle excitable. The knee-jerks and other tendon reflexes were normal. His pulse had not slowed, his respiration was unembarrassed; the condition of his pupils could not be ascertained as homatropine had been instilled for examination of the discs, which were normal. In short, the case presented paralysis of two nerves: the seventh and sixth. Paralytic symptoms, the onset of which is delayed for some days after the infliction of the head injury strongly point, Mr. Edmunds said, to venous hæmorrhage, and the whole aspect of this case was consistent with this view.

The fact that the whole of the muscles supplied by the facial nerve were equally involved pointed to a lesion of the nerve trunk beyond its nucleus and the implication of the sixth nerve as well suggested that the lesion would be found at or near the apex of the petrous portion of the left temporal bone. The slow onset of the symptoms and the absence of any very marked signs of cerebral compression pointed as before referred to. Venous extravasation, hæmorrhage from the lateral sinus would account quite satisfactorily for the symptoms; the blood in this region tends to be confined beneath the tentorium and would exert pressure on nerves in the vicinity without affecting the cerebral hemispheres as a whole. Acting on this diagnosis the patient was anæsthetised, the head shaved and a large flap turned down over the left side of the occipital bone. The skull was trephined over the left lobe of the cerebellum and a sufficient quantity of bone was removed; the dura mater bulged, but did not pulsate. This membrane was now incised and a finger insinuated along the wall of the posterior fossa towards the internal auditory meatus; on withdrawing the finger there was a sharp spurt of blood from the tracts which had been thus temporarily opened up. Hæmorrhage from venous sinuses was not, as a rule, Mr. Edmund said, serious as regards loss of blood, and accordingly it was thought sufficient to pack gauze on to the site of the bleeding so as to allow for any further extravasated blood to escape. The wound was sutured, leaving an opening through which the gauze could be withdrawn. The patient was put back to bed when his condition, unfortunately, did not improve; he gradually became comatose and died.

At the *post-mortem* it was found that there was a fracture of the base of the skull, involving the tip of the petrous portion of the temporal and lacerating the lateral sinus. Hæmorrhage from this region had been relieved, but there was a considerable amount of hæmorrhage round the medulla and cord which had led to the fatal issue.

Measles Epidemic Subsiding.—The measles epidemic which has been raging in Nottingham for three months is showing signs of subsiding. Only eight deaths from this cause were reported last week. Altogether, over 220 children have died from measles in Nottingham.

TRANSACTIONS OF SOCIETIES.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of Medicine.

President—J. M. **Redmond**, M.D., P.R.C.P.I.
Sectional Secretary—F. C. **Purser**, M.D., F.R.C.P.I.

Meeting held Friday, May 17th, 1907.

Dr. **Kirkpatrick** in the Chair.

LYMPHO-SARCOMA IN THE LEFT LUNG.

Dr. **Craig** read the clinical notes on a case of lympho-sarcoma of the left lung, and exhibited the *post-mortem* specimen. The patient was a man, æt. 46, who thought he had caught a cold in October, 1906. He was treated in hospital for bronchitis. His most marked symptoms at that time were orthopnœa, cough, and occasional blood-stained sputum. He came under Dr. Craig's care on March 12th, 1907. He had orthopnœa, cough, frothy expectoration, œdema of the lower limbs, slight ascites, albuminuria, systolic aortic murmur. The left lung showed physical signs of complete solidification, with thickened pleura. His abdomen was tapped on March 30th, 1907, and chylous fluid drawn off. His voice became husky, and he had severe pain over the cardiac region. He died on April 4th 1907. *Post-mortem* revealed chylous fluid in the abdomen, enlarged and congested liver; nothing else abnormal. Pericardium was distended with sanguineous fluid and subserous hæmorrhages were observed in many spots. Cardiac valves were healthy. A white opaque, homogeneous spherical tumour occupied the greater portion of the left lung. Section of enlarged lymphatic glands showed in the substance of the tumour. Secondary growths were present in the rim of lung tissue which the primary growth had not invaded. Portions of the tumour extended along the course of the left pulmonary veins, pulmonary artery, and the aorta, so as to appear within the pericardium. The entire adherent left pleura was about one-eighth of an inch in thickness, but had no connection with the tumour. The tumour appeared to have started in the bronchial glands and spread outwards.

SOME CASES OF TUBERCULOSIS TREATED BY PROFESSOR DENY'S TUBERCULIN.

Dr. **Frank J. Dunne** exhibited six cases of tuberculosis treated by Professor Deny's tuberculin in the South Dublin Union Hospital.

The **Chairman** desired to know if Dr. Dunne considered that the local and general reaction, which was so marked in some of the cases, was a necessity, or whether it would not be better to reduce the dose, so as to reduce the initial reaction, and try and spread it over a longer period.

Dr. **Stevenson** showed X-ray photographs of the case, in which the wrist was involved and said he could not say from the photographs alone whether there was any disease in the bone; clinically there did not seem to be any disease now, but the photograph simply showed that there had been diseased bone removed.

Dr. **Craig**, General Secretary, expressed the thanks of those present to Dr. Dunne for his exhibits; they were, he said, greatly impressed by the excellent results obtained, and highly appreciated Dr. Dunne's work.

Dr. **Moorhead** asked if the cases were all in which the treatment had been tried, or were a selection. He had seen two of them when they were very bad, and was much impressed with the improvement. He was also desirous to know if Dr. Dunne had found the opsonic index raised by the injection of Deny's tuberculin.

Dr. **Dunne**, in reply, said he agreed with the Chairman, in regard to the reduction of the dose. In fact, he commenced the girl with the wrist with five parts in a million, and did not know what would have happened if he had given her the dose of half a milligramme, which is recommended of Koch's tuberculin. Tuberculin at present had to be used with very great care, and he believed the ordinary trial doses were too stron The cases were selected from the one-third of the tot (150) which he injected. He selected them becau they were affected in a way that could be seen; b many of his pulmonary cases—which were difficult t demonstrate—were quite as good. He hoped later t present a tabulated return; pressure of work ha prevented his making it, as well as trying the opson index.

AN OBSCURE CASE OF NERVOUS DISEASE.

Dr. **Winter** exhibited an obscure case of nervou disease. The symptoms were, he said, vague. The mai thing was exaggerated reflexes, and the patient had a sensation, sometimes of pain and sometimes of numbness and tingling, in his left arm and leg when he go out of bed. Sometimes he got a spasm in his calf an the three outer fingers of his left hand. His superficia reflexes were normal.

The **Chairman** said he would hesitate to diagno the case. There were a number of points which rendered it almost certain that it was a case of disseminated sclerosis; but he was not familiar with th marked spasm as a symptom.

A CASE OF SPLENO-MEDULLARY LEUKÆMIA.

Dr. **A. R. Parsons** read a paper on a case of spleno-medullary leukæmia which had undergone a very remarkable improvement under treatment with arsen —improvement both in the size of the spleen and th condition of the blood.

Dr. **Craig** recalled a case in which the spleen unde arsenic treatment, used to disappear quite beneath the costal arch, so much so that he thought the man was cured. He returned, however, a couple of times to hospital, although taking fairly large quantities o arsenic. In the end he died of general tuberculos and at the time of death the spleen was fairly larg though not so large as on previous occasions. Dr Parsons had shown them a remarkable cure, but wit his own case in view, he would hesitate before sayin that the condition would not recur.

The **Chairman** asked Dr. Parsons if he had formulated any opinion as to the relative merits of the treatment by arsenic and by X-rays, or by both in combination. Dr. Craig's case showed that it was possible to cause the disappearance of the symptoms by drugs but it was important to find whether not only a disappearance of the symptom, but a cure, could be effecte by the X-rays.

Dr. **Drury** cited the case of a woman who had a much larger spleen than Dr. Parson's case. Every drug treatment was tried without result. Then they tried the X-ray treatment alone, and the spleen was enormousl reduced. Ultimately she died of syncope.

Dr. **Parsons**, in reply, said he had purposely avoide using the word *cured*. So far as he knew there was no case of *cure* on record. The improvement in the cas had continued even after the arsenic was stopped. In another case, a lady, æt. 55, who had bee on arsenic for about five months, the treatment had produced diarrhœa and vomiting. She then cam to him, and, as the arsenic had made no improvement he put her under X-rays. After twenty sittings th spleen commenced to subside, and there was also a marked diminution in the white corpuscles. The case therefore proved that the X-rays alone could brin about a remarkable improvement.

NOTES ON A CASE OF CEREBELLAR-PONTINE CYST.

Dr. **Peacocke** read notes of a case of cerebellar-pontine cyst, which occurred in a man æt. 30. His symptoms were frontal headache, giddiness an staggering gait, failing sight, and deafness of the le ear. There was no vomiting. Examination showe paralysis of the muscles supplied by the seventh nerv on the left side, and loss of sensation in the left side o the face. There was no loss of power or sensation in the legs or arms. The thoracic and abdominal organ were healthy. Examination of the eye showed optic neuritis, with small hæmorrhages and white patch in the neighbourhood of the optic disc. There was no elevation of temperature, and the pulse was norma He died quite suddenly, about six months after th first onset of symptoms. *Post mortem* made thirty hours after death, showed a cystic growth involving both cerebellum and pons on the left side. Microscopic examination showed that the brain tissue adjoining the cysts showed two different tissues:—(1) Composed of spindle-shaped elements very cellular, and resembling in all respects a spindle-celled sarcoma. (2) A tissue composed of smaller cells (neuroglial).

Dr. Parsons said that hardly any cases were more trying than brain cases, and he desired to know if the question of operative inferference had been raised. If the surgeon had been able to strike the cyst, the eyesight might have been saved.

Dr. Craig instanced a case in which loss of hearing gave a fair opportunity of localising the tumour, but the operation failed, and the girl died.

Dr. Moorhead said the question raised by Dr. Parsons was very important. In cases where localising symptoms made the position certain, he thought that early operation should be recommended.

Dr. Peacocke, in reply said that the question of operation did suggest itself to him, but no one else who saw the case suggested it.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

Meeting held at Edinburgh, May 25th, 1907.

The President, Priestley Smith, F.R.C.S., in the Chair.

Mr. George Coats gave a lantern demonstration on the pathology of rupture of Descemet's membrane. They were first discovered microscopically by Becker, in 1875. Coats had found them in 12 out of 13 cases of buphthalmos, and in 2 out of 8 cases of glioma with increased tension. They were absent in 4 cases of high myopia. The ruptured ends were sometimes found to be flat, and sometimes curled up, but the rupture itself was almost always covered with endothelium. At times extensive detachment of the membrane was found.

Experimentally he found that the globe would give way before the membrane would rupture, but if the membrane was first scratched, many fractures of the rupture could be reproduced.

Dr. Edridge-Green gave an account of his observations with Lord Rayleigh's colour-mixing apparatus, and showed a table which brought out the fact that there were extraordinary differences in the way in which people were able to match the colours. This was not due to any physical condition present, but could be readily explained physiologically in accordance with the author's theory of colour vision.

Dr. Alexander Bruce gave a lucid lantern demonstration of the third nerve nucleus and its surrounding parts.

Mr. Sydney Stephenson described the present position of the spirochæta pallida in relation to syphilitic affections of the eye. After briefly reviewing the evidence in favour of the spirochæta pallida being the specific element of syphilis, he described the special researches which had been made on the eyes of man and the lower animals. In congenital syphilis the organism had been found by Stock, Peters, Römer, Bab, and himself. He detailed the experiments of other observers who had produced interstitial keratitis in the eyes of monkeys and rabbits with syphilitic material from man, and had found spirochæte in the lesions thereby produced. As regards clinical syphilis of the eye, the organism had been found by himself and other observers, and he expressed his belief that the presence of Schandinu's organism was the strongest possible proof of the syphilitic nature of any given disease of the eye or of any of its appendages.

Dr. Leslie Buchanan showed a series of lantern slides of preparations of eyes of invertebrates, with the object of indicating that from the anatomical structure, a certain amount of information can be obtained as to the degree of functional activity of which the organ is capable. The preparations included sections of the eye of the octopus, the clam, the spider, the caterpillar, the house fly, the bee and the snail. Sections of the eye of the Australian mole and of the leech were shown to illustrate the fact that loss of functional activity leads to anatomical degeneration.

Dr. Buchanan also demonstrated a case of rupture of the pectinate ligament. A man was struck on the left eye by a broom handle in the end of June, 1906. Amongst other injuries to the eye, there was what appeared to be a large coloboma of the iris in a downward and inward direction, accompanied by high tension and loss of vision. The case was considered to be one of rupture of the pectinate ligament, with displacement of the iris and ciliary body backwards along the sclera. As the eye continued to be painful, it was excised in January, 1907, when, after histological examination, the diagnosis was proved to be correct. Microscopic preparations were shown.

Dr. Angus McGillivray read a paper on the treatment of after-cataract. To obviate the dragging on the ciliary body and the risk of cyclitis, he divides the capsule diagonally from above downwards and inwards by very short and steady sawing movements by means of a specially-designed cutting needle. Since adopting this sawing method of dividing opaque capsule after cataract extraction, little or no trouble had been experienced, so little, in fact, that he does not now hesitate to divide an opaque capsule when the vision is, from this cause, below $\frac{6}{12}$.

Dr. McGillivray also showed a very convenient storage battery for ophthalmic use.

Dr. Arthur Sinclair and Dr. Theodore Shennan described a case of Parinaud's conjunctivitis in a man, æt. 61, who was a painter's labourer. The left eye became affected during the third week in July, 1906. About three weeks later the surrounding lymphatic glands became enlarged. The patient was under observation for four months, and had not completely recovered when he ceased his attendance and could not be further traced.

Dr. Shennan described carefully the histological and bacteriological condition found. Two varieties of staphylococci were the organisms found.

Dr. Inglis Pollock described a case of telangiectasis of the retinal capillaries and venous radicles. The condition followed on fracture of the left side of the skull, due to a heavy weight falling upon the patient's head. He showed an opthalmoscopic drawing of the fundus.

Numerous card specimens were shown.

Dr. Arthur Sinclair showed a collapsible apparatus for testing the field of vision. He also showed the charts from a case of glaucoma, showing remarkable restriction of the fields of vision in both eyes.

He also showed a case of retinitis punctata albescens.

Dr. Alexander Bruce showed two cases of intracranial neoplasms.

Dr. Robert Fleming gave a microscopical demonstration of an optic neuritis in relation to intracranial tumours, with special reference to the changes in the neuroglia cells.

Dr. E. Bramwell exhibited a brain showing occipital abscess from a case in which epileptic fits were preceded by visual auræ and in which hemiachromatopsia developed. Also a case of ocular palsy, with congenital absence of cranial nerve nuclei.

Mr. Berry showed several cases. He exhibited a loupe for the use of myopes, and test objects for illiterates.

Dr. Mackay exhibited some unusual clinical cases and coloured drawings.

Dr. Sym showed a case of complete congenital anophthalmos and other cases.

Dr. J. V. Paterson showed a case of tubercle of the conjunctiva, and a very pretty case of reticular keratitis.

Dr. Maitland Ramsay exhibited an opaque projector for teaching purposes and some pathological specimens.

Lieut.-Colonel Herbert, I.M.S., gave a lantern demonstration of the sinuous lid border as a sign of trachoma.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, June 10th, 1907.

A Sure Sign of Pulmonary Tuberculosis.

Dr. Roux, of the Pasteur Institute, made a highly interesting communication before the meeting of the Académie des Sciences in reference to the diagnosis of consumption in its earliest stage, that is, before any tangible symptom, objective or subjective, can be discovered. The method, which was first indicated by Dr. Pirquet, of Vienna, consists simply in making a small incision in the skin as for vaccination, and rubbing in two or three drops of tuberculin of Koch. If the disease is not present, the incision heals rapidly without trouble; if, on the contrary, the patient is in the slightest way touched with the bacilli of Koch, the little wound becomes inflamed, and in five or six days a pustule appears, which, in its turn, dries up in a few days.

Similar experiments were made on animals by Professor Vallé, of the Veterinary School at Alfort, near Paris, and the same results were observed. He vaccinated healthy and tuberculous cows. In the former, the skin showed no signs of reaction, while in the latter the parts became swollen for a few days. As it is allowed by all modern authorities, and confirmed by facts, that phthisis can be cured if treated in its incipient stage, the importance of the above communication is far-reaching and cannot escape the attention not only of all practitioners, but also of the public at large. Other experiments are being made in the Paris hospitals to verify the statements of the director of the Pasteur Institute.

Specific Treatment of Grippe.

Dr. Barbary, of Nice, had a paper read at the Académie de Médecine, on the treatment of grippe by injections of one grain of cacodylate of guaicol in water. Over 100 cases were treated with success and the conclusion he arrived at was that cacodylate of guaicol was a real specific for grippe.

Ice Over the Heart in Febrile Diseases.

Professor Leduc strongly recommends the placing of the ice-bag over the heart as a powerful means of strengthening the organ in the course of high temperatures by which it is weakened in its energy.

This precordial frigo-therapy gives the same results as the cold bath, and has the advantage of easy application.

In all febrile maladies, where the fever is over 102° and the pulse over 110, the ice-bag should be applied; one or two folds of flannel should be placed between the skin and the ice.

Within two hours after the application, the temperature falls one or two degrees, while the pulse diminishes by fifteen to thirty beats and regains its strength.

No medical antithermic agent can act as regularly and as surely.

Under its influence a general improvement takes place in all the functions and in particular those of the nervous system.

When the temperature has remained for several days sufficiently low, the ice-bag may be removed, but frequently the temperature goes up again. The better plan would be to diminish gradually the antithermic action by doubling the folds of flannel.

One curious effect of this treatment is that it increases the antithermic action of pyramidon and quinine. A dose of ten grains of pyramidon which, before, had no effect on the fever, produced, after the application of the ice-bag, a sudden fall of the temperature with profuse perspiration, endangering the patient's life. Two grains of pyramidon were quite sufficient to obtain the desired result in all cases.

Professor Leduc concludes that the ice-bag should be applied to all patients whose temperature exceeded 102°.

GERMANY.

Berlin, June 9th, 1907.

At the Verein für Innere Medizin, Hr. Benda related a case of

Blastomycosis of the Brain.

On March 22nd, a body came from the Second Medical Abteilung of the Urban Hospital with a diagnosis of encephalitis. The autopsy showed first hyperæmia and clouding of the meninges, but no proper inflammation. On opening the ventricle small white mucous threads were seen in the otherwise clear fluid. On microscopical examination these were found to be small, rounded bodies, strongly refracted, light, and of irregular size. This led the examiner to say that they looked like the cells of the yeast fungus. This suspicion was confirmed on further examination, as by both staining and pure cultivation, they proved to be really yeast cells. The meninges were then found to be strewn with the cells. Macroscopically, on the brain surface were numerous vesicles, and in the cortex were numerous small cavities from the size of a millet to that of a hemp seed. The basal ganglia were also strewn with them. Microscopical examination showed that the patches consisted almost entirely of yeast cells. There had been no real inflammation, the only things seen were macrophaga filled full of yeast cells. Culture of the cells showed some biological peculiarities. They did not ferment, and were very oxyphile. No pathological explanation of the case could be given. No port of entrance could be made out; nothing was found in the frontal sinuses, and in the lungs there was no blastomycosis, only pneumonia. A similar case occurred at the Friedrich's Narri Hospital.

Hr. V. Hausemann remarked that the case at Friedrich's Narri was a similar one. A third case was observed recently in Vienna, but it had not yet been published. In his case, Krönlein had found the cells in the cerebro-spinal fluid after lumbar puncture, so that the condition was diagnosed *intra vitam*.

Hr. Plehn observed that in Benda's case, which had come from his own Abterlung, the yeast cells were also found in the fluid from the spinal punctures, but death took place before the examination was completed. As regarded clinical symptoms, the patient had had an attack of influenza a few weeks before, had recovered, and had again sickened with fever and somnolence. There were no brain symptoms whilst the patient was in hospital, the ophthalmoscope showed neuro-retinitis.

Hr. Grawitz showed a case of

Addison's Disease in which Recovery has Taken Place,

with observations on the pathogenesis of the disease He remarked that recovery from Addison's disease was so rare that such a case was extremely interesting. The patient, an official of the Charlottenburg Magistracy, entered his regiment as a one year recruit in 1902, and performed his duties with satisfaction for a time. During his free hours he occupied himself extensively with mental work, in order to prepare himself for the secretary's examination. His health suffered, however, and he spent some time in hospital. In November, 1902, he relapsed, had a brown look and as he got steadily weaker, he was admitted into hospital again; from here he was at last discharged from military service. He came into the Charlottenburg hospital early in 1903. There was strong pigmentation of the hands and face and of the axillæ, great weakness, intense gastro-intestinal symptoms, motor and functional insufficiency. The impression he gave was a bad one. The directions given were for washing out of the stomach, the injection of food into it, and nutrient enemata; no medicines. The nourishment was practically vegetable, albuminous material was only given in the enemata. The condition improved much, the strength increased. In three weeks the man gained 3 kgrm. in weight, the pigmentation was unchanged. The patient was discharged from hospital and sent to Thuringia for further recuperation. He lost ground there, however, and came back in a wretched state, strong adynamia, and the old pigmentation. The treatment was begun again with the same improvement, the pigmentation failed, and he was again discharged to service in the Bureau. Examination of the stomach showed absence of free hydrochloric acid. The patient followed a rigid *regime*, took no alcohol, and, since his discharge, he had been able to perform his duties. The pigmentation had almost disappeared. There was a slight trace on the lips only. During the last few weeks the patient had had a tuberculous testicle removed; otherwise no tuberculous signs were present.

In many cases of Addison's disease no change had been found in the supra-renal capsule, and also in many cases of disease of the capsules no bronzing was present. A chromophile substance had been shown to be present in the medullary substance of the supra-renal capsule, and the notion had been propounded that Addison's disease was associated with the loss of this substance. The question now arose whether this disease was an ætiological entity. We saw in the so-called "Vagabond's Disease" a similar pigmentation of the skin, which, according to Neisier, depended on the miserable condition of the body. Now in lethal diseases, pernicious anæmia for example, any demonstrable anatomical cause was sometimes not to be found. Perhaps it was the same with Addison's disease. How had treatment done its work in this case? Here it was to be observed that similar treatment was successful in intestinal pernicious anæmia. Perhaps toxic products were absorbed through the severe intestinal catarrh, that acted unfavourably on the function of the supra-renal capsules. It was well indicated, therefore, in cases of Addison's disease with intestinal symptoms to act on the intestines in the way pointed out.

AUSTRIA.

Vienna, June 9th, 1907.

Thyroid Epithelial Corpuscles.

Leischner gave his long promised report to the members of the Gesellschalft on his experiments with animals in removing the thyroid gland. Other experimentors have found that when the epithelial bodies are retained in the gland tetany is obviated. This has now been acknowledged by all operators, but the question arose: could the function of these epithelial corpuscles be retained if transplanted to the remaining portion of the gland? Leischner answers in the affirmative and avows that where the surgeon has a severe operation and must remove a large part of the thyroid gland, he should search in the part removed for every epithelial corpuscle he can find and transplant them into the portion of gland left in the wound, as he has done in animals with perfect success. Where intra-cystic enucleation is necessary, every epithelial body should be retained to avoid tetany.

Eiselberg said he had performed many operations lately for goitre, and has now set it down as a general rule that the fewer epithelial bodies you remove the greater is the success in recovery. He has also learned that one cyst can be removed from the human subject without doing much harm as the other three are quite able to perform the necessary functions of the body.

Aniridia Congenita.

Bergmeister next presented two patients with eyes having no irises, permitting the lens to fall forward on the cornea, producing ectopia lentis. In one of the cases the mother, æt. 42, and another daughter, æt. 10, had a similar congenital defect. The daughter's scleral surface had a porcelain appearance, with firm resistance to touch while the ciliary vessels had nothing abnormal. Astigmatism of 2½ dioptres was present, while the anterior chamber had a normal depth, but both irises were absent. The lens lay obliquely so that light from the side produced darkness although the lens was perfectly clear and transparent. The fundus of the eye was normal and strong light almost blinded the patient. Acuity of vision was reduced to one-tenth, and could read at 7 to 12 ctms. distant. Looking through an orifice of 1 millimetre the vision was improved three times, or ⅓. In the second case the mother suffered from glaucoma in both eyes, the bulbi being rigid, hard, and the cornea projecting and densely clouded, the left more than the right; in the latter around the cornea the absence of the iris could be observed as in the daughter.

In congenital aniridia glaucoma is a common result, which usually defies all treatment, and as iridectomy is impossible sclerotomy is the only relief which has never given any good result. In this case he thought "kyklo dialysis" as practised by Heine in glaucoma, might be of some service.

Carcinoma Mammæ.

Riehl showed a cast of a carcinomatous mammæ which came under his notice for treatment, and which was so peculiar that he has not yet found a description in medical literature that elucidates his case. The disease was distributed over the gland in small vesicular groups from a millet seed to the size of a pea, at first filled with clear fluid, but later tinged with blood. These miliary vesicles felt hard and resisting, and remained weeks in this condition till they collapsed by exudating matter, and on being pricked early discharged clear fluid. In these cysts very few epithelial cells of carcinoma were present at first, but at a later period they appeared at the base of the cavity increasing in number till a hard nodule was formed. These small cysts appear to have developed primarily in the lymphatic vessels, whose endothelium formed the sac and from which the carcinomatous cells wandered in the lymph vessel till another was formed, thus repeating themselves by metastasis, finally producing a wide area of carcinomatous tissue. The bleeding resulted from the destruction of the capilliary vessels and blocking of the circulation, as in lymphangioma.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

Edinburgh Royal Infirmary.—At their meeting on June 3rd the managers promoted Dr. William Russell, assistant physician, and Mr. J. W. B. Hodsdon assistant surgeon, to the posts of ordinary physician and surgeon to the institutions. These appointments date from September 1st next, when Dr. James and Mr. MacGillivray, the senior physician and surgeon, domit office. There are now vacancies for an assistant physician and surgeon, and for these posts a number of candidates are in the field.

Edinburgh and Glasgow Medical Club.—The annual dinner of this club took place on May 31st in the College of Physicians, Dr. Playfair being in the chair. The club is purely of a social nature, and this dinner was unusually successful, as a much larger contingent of Glasgow members attended than is usual. The next dinner takes place in Glasgow, and it is expected that the attendance of Edinburgh members will be good. Such meetings do much to encourage friendly feeling between the members of the profession in the two cities, and to remove those sentiments of jealousy which are sometimes a hindrance to the advance of medicine.

Sir Henry Littlejohn's Annual Report on the Health of Edinburgh.—A Summary of this report, which is not yet in the hands of the public, has been issued. The birth rate of 22.41 per 1,000 is still on the down grade, and is lower than many other large towns save Perth. The death rate is 16 per 1,000, or deducting temporary residents and those who had come into the city for treatment, 1,426, practically the same as in 1905. The low death rate is in keeping with the steady reduction of the past twenty years. The zymotic death rate (excluding diarrhœa) was ·75 per 1,000, which is considerably below the five years' average of 1·25. No small-pox or typhus have occurred during the year. The deaths from phthisis and other tuberculous diseases show a decline. Typhoid fever is diminishing, whereas diphtheria has increased in frequency.

BELFAST.

Sewage Purification.—At a recent meeting of the Belfast Corporation particulars were given of the progress of the new sewage purification works. The experiments which have been carried on for some years have shown the best lines on which to treat the sewage, having regard to the peculiar conditions which prevail in Belfast Lough, and plans are being made to construct large septic tanks. Meantime the works already constructed are capable of dealing with one-sixth of the sewage of the city, obtaining a purification, judged by the free ammonia, of 60 per cent., while the new tanks, by means of sprinkling beds, will give a purification of 96 to 98 per cent. If this sanguine forecast proves correct, it will be a real boon to the city and neighbourhood, to which the state of the Lough caused by the sewage discharged into it has for years been a very real nuisance.

Mater Infirmorum Hospital, Belfast.—The annual report of this hospital, just issued, shows a large amount of vigorous and successful work on the part of the medical staff. During the past year the intern patients numbered 1,861, the surgical operations performed were 597, the accidents treated were 4,268, and the total number of patients treated in the extern department was 29,914. The total expenditure for the year was £5,100.

Cerebro-Spinal Meningitis.—During last week there were 22 cases of cerebro-spinal meningitis notified, the same as the week before. The deaths registered were 14, which is six less than the previous week, and there seems no doubt that the disease is showing a less virulent character than it did some weeks ago.

LETTERS TO THE EDITOR.

DOCTRINA.

To the Editor of The Medical Press and Circular.

Sir,—Although I naturally feel much interest in reading the excellent letters on the hospital question which your correspondents have addressed to you on this important subject, may I this week direct some attention to the question of education, which is at last beginning to attract such men as Mr. Balfour and others, who are gradually beginning to realise that reforms in universities and education generally are important matters? The question of interest to us is how to educate our rising doctors. We want those who are entering the profession to come with something more practical and less assertive or conceited than we fear is the consequence of cramming and examinations. I remember Sir William Lawrence telling me how he lived in the house of Abernethy, and how he learnt his art and science from that distinguished man. There is no doubt but that we feel very great interest in hospitals, not as charitable institutions, but as schools of medicine and surgery; and we cannot but regret that as such they have degenerated sadly from what they were in the time of the Hunters, Astley Cooper, Matthew Baillie, and the leaders of the early and middle periods of last century. To get the courses signed up, after paying the necessary fees, seems to be of more importance to the student now than learning anything from lectures. It is the examinations upon which the students' mind is fixed; and when these are over, then he may begin to learn. Mr. Balfour seems to think much of post-graduate study. He may perhaps not be familiar with the Hippocrates dictum—"Life is short; art is long; the opportunity fleeting." The post-graduate principle is somewhat like the Chinese. It would be well to be careful we don't drift into such a state as they have.—I am, Sir, yours truly,

R. L.

A PERINEAL HORN.

To the Editor of The Medical Press and Circular.

Sir,—The appliance described under above heading by Dr. Elliott in the last issue of your journal, is not new. Twenty years ago I designed and used a similar retractor, and found it a failure. Laceration depending very often more on the size of shoulders of the fœtus (and perhaps their unskilful delivery) than the size of fœtal head. A far simpler plan and one for which I claim priority, is the following which has *never yet failed me* in preserving intact the perineum (should I see the case in time), viz. intermittent traction backwards of the perineum during (and only during) the continuance of each pain, in humble imitation of nature, the dilatation of the os and cervix being effected in a similar way.

I am, Sir, yours truly,

London, W. Alexander Duke.

MEDICAL MEN AND NURSING HOMES.

To the Editor of The Medical Press and Circular.

Sir,—I am deeply pained to find that a limited liability company has been registered this week to run a nursing home, and that most of the shareholders signing, and nearly all the directors, are Fellows of the Irish College of Physicians.

I should not hesitate to detail the names of those doctors, were it not for the great personal respect which I have for them, but they must surely see, on reflection, that such a position is incompatible with the dignity of a Fellow of the College.

The rules forbid a Fellow to supply medicines, or even to be interested in a compounding establishment, so that nobody can suggest that he profits out of the drugs he orders; but certainly it is of far more importance that nobody could say that the physician will profit when he recommends a patient to a private hospital for some time.

Of course, the gentlemen in question are above suspicion, but their example will tempt humbler men to follow—with lamentable results.

I am, Sir, yours truly.,

J. C. McWalter.

OBITUARY.

J. S. HICKS, F.R.C.S.Ed., L.R.C.P., F.L.S.

We regret to announce the death, on June 1st, of Dr. John Sibley Hicks, of Sefton Park. The deceased gentleman served for some years as a medical attendant on one of the liners sailing between Liverpool and America, and finally settled in Liverpool, where he had practised for the last forty years. He was educated at Glasgow University and qualified as L.F.P.S. and L.M. in 1860. In 1871 he took the F.R.C.S.Ed. and L.R.C.P.Lond. He was much interested in natural history and microscopy all his life, and was an F.L.S. and F.R.M.S.

THOMAS M. BELLEW, L.R.C.S.I.

We regret to announce the death of Dr. Thomas Mulholland Bellew, of St. Helens, which occurred after a long and painful illness on June 4th. Dr. Bellew was a native of Strinagh, near Drogheda, but he had been in practice in St. Helens for the past twenty-five years, during which time he had been most popular. He was surgeon for the Lowe House Men's Guild, Holy Cross Boys' Guild, the Great Central Railway, and two of the local copper and smelting works. Over a year ago he was attacked by a serious malady, for which since October last, three operations had been performed. He leaves a widow and five children, with whom the greatest sympathy is expressed.

WILLIAM MAULE, M.B., C.M.Ed.

We regret to announce that Dr. William Maule, of Birkdale, and formerly of Wigan, died on June 2nd., aged fifty-four. He had been in failing health since February. He studied medicine at Edinburgh, and after qualifying in 1876 as L.R.C.S. and L.M., he proceeded to read for the University final, which he passed in 1879. He was surgeon to the Great Central Railway at Birkdale, and was known as author of "Medical Tracts for the Times."

SPECIAL ARTICLE.

THE IRISH UNIVERSITY QUESTION.

In the House of Commons last Monday the Prime Minister said :—

"It is clear to the Government, in regard to another great question, that of University education in Ireland, that no practical result could be expected to follow the introduction during the present session of a bill dealing with the question. During the autumn recess my right hon. friend, the Chief Secretary, contemplates being in Ireland, and devoting time and attention to the question. My friend the right hon. gentleman is of a cheerful and often sanguine temperament, and he believes that it is possible, and even likely, that there may be established or discovered harmony among the jarring interests and views upon the subject in Ireland—a task which I admit has often defied the efforts of the pacificator.

Mr. John Redmond said :—

"I confess I heard with great regret the statement made by the Prime Minister on the University question. Let me in two or three sentences recall to the memory of the House how the matter stands. The late Government declared that they could not deal with this question until there was practical unanimity of opinion in Ireland. That meant, of course, the practical shelving of the question, because you never can have practical unanimity on a question of this kind in Ireland any more than you can have practical unanimity of opinion on any educational question in England. Now, whatever differences there may have been as to the merits of the scheme in comparison with other schemes previously suggested, that at any rate was the result of that action—that all those who represented at any rate Catholic and national opinion, came out and declared that they would accept his scheme. The representatives of the Irish National party said so, the Irish Hierarchy said so, and practically all those in Ireland who may be classed in the terms Nationalist and Catholic declared that they would accept the scheme, although in many cases it was not the one that they individually would have preferred. But now, not only is the Government not going to introduce this bill this session, but we are face to face with the fact that they are not going to introduce it. I did not believe that they could pass it this session, but I did believe they could introduce it, as they are doing with reference to another bill mentioned, and introduce it for discussion in the autumn during the recess. Not only that, however, but they have absolutely reverted to the policy of their predecessors—that is to say, they (the Prime Minister and the Chief Secretary) are to spend time in discussing a scheme that will unite everybody in Ireland. Well, that is an impossible task. No one knows it more than the Chief Secretary himself, and I think it is most lamentable that this backward movement should be taken upon this question."

NEW BOOKS AND NEW EDITIONS.

The following have been received for review since the publication of our last monthly list :—

Sidney Appleton (London).
Physical Diagnosis. By Howard S. Anders, A.M., M.D. Illustrated. Pp. 456. Price 12s. 6d. net.
Bailliere, Tindall and Cox (London).
"A Synopsis of the British Pharmacopœia" (1898). By H. Wippell Gadd, F.C.S. Sixth Edition, containing a synopsis of the Poison Laws of Great Britain and Ireland. Pp. 227. Price 1s. net.
On Treatment. By Harry Campbell, M.D., B.S., F.R.C.P., Physician to the N.W. London Hospital &c. Pp. 421. Price 5s. net.
Rational and Effective Treatment of Hip-Disease By P. Bruce Bennie, M.A., M.D., B.S.(Melb.). Compiled by Alex. B. Bennie, M.A., M.B., B.S.(Melb.). Illustrated. Pp. 108. Price 5s. net.
A Dictionary of Medical Diagnosis for the use of Medical Practitioners and Students. By Henry Lawrence McKisack, M.D., M.R.C.P. Lond. Illustrated. Pp. 583. Price 10s. 6d. net.
John Bale, Sons and Danielsson, Ltd. (London).
The Psycho-Physical Aspect of Climate with a Theory Concerning Intensities of Sensation. By W. F. Tyler, F.R. Met. Society. Pp. 45. Price 5s. net.
George Bell and Sons (London).
The Gem-Cutter's Craft. By Leopold Claremont. Illustrated. Pp. 296. Price 15s. net.
Blackie and Son, Ltd. (London).
The Laws of Health : A Handbook on School Hygiene. By Carstairs C. Douglas, M.D., D.Sc., F.R.S.E. Illustrated. Pp. 240.
J. and A. Churchill (London).
St. Thomas's Hospital Reports. New Series. Edited by Dr. H. J. Turney and W. H. Battle. Vol. 34. Pp. 637. Price 8s. 6d. net.
Materia Medica Pharmacy, Pharmacology and Therapeutics. By W. Hale White, M.D., F.R.C.P. 10th Edition. Pp. 692. Price 6s. 6d. net.
Henry J. Glaisher (London).
Hay-Fever, Hay-Asthma: Its Causes, Diagnosis and Treatment. By William Lloyd. Pp. 95. Price 3s. 6d. net.
"The Guardian" Office. (London).
Our Sons: Their Start in Life. With Two Articles on Professions and Occupations for Women. 2nd Edition. Pp. 122. Price 2s. 6d.
The Health Resorts Bureau (London).
Some Summer Resorts in the South of France. By John W. Potter. Second Edition, enlarged. Pp. 134. Price 1s. 6d. net.
Henry Kimpton (London).
Medical Philosophy. By W. Russell. Pp. 504. Price 21s. net.
H. K. Lewis (London).
Modern Methods of Diagnosis in Urinary Surgery. By Edward Deanesly, M.D., B.Sc.Lond., F.R.C.S. Pp. 97. Price 3s.
McCorquodale and Co., Ltd. (London).
Metropolitan Asylums Board. Annual Report for the Year 1906. Pp. 350. Price 5s.
Macmillan and Co., Ltd. (London).
Alcohol and the Human Body. By Sir Victor Horsley, F.R.S., F.R.C.S., &c., &c., and Mary D. Sturge, M.D.Lond., with a chapter by Arthur Newsholme, M.D., &c., &c. Pp. 370. Price 5s. net.
G. P. Putnam's Sons (London).
The Muscles of the Eye. By Lucien Howe, M.A., M.D. In two volumes. Vol. I. Anatomy and Physiology. Illustrated. Pp. 455. Price 16s. net.
A Manual of Prescription Writing. By Matthew D. Mann, M.D., A.M., M.D. Revised by E. C. Mann, M.D. Sixth Edition. Pp. 232. Price 4s. net.
Rebman, Ltd. (London).
On Benign Cysts of the Long Bones. By Robert Jones, F.R.C.S., and Dr. David Morgan. Reprinted from "Archives of the Rontgen Ray and Allied Phenomena," April and May, 1907. Pp. 4.
F. R. de Rudeval (Paris).
Précis de Technique Orthopœdique. By P. Redard. Illustrated. Pp. 591. Price 12 frs.
La Grande Faucheuse. By Dr. Fernand Barbury. Illustrated. Pp. 340 Price 7 frs.
Alex. Thorn and Co., Ltd. (Dublin).
The Royal University of Ireland. The Calendar for the Year 1907. Pp. 547.
F. S. Turney (London).
Medical Priestcraft. A National Peril. By John Shaw, M.D.Lond. Pp. 246. Price 5s. net.
Cancer: A Working Theory for its Prevention and Cure. By John Shaw, M.D.Lond. Pp. 25. Price 1s. net.
J. J. Weber (Leipzig).
Deutsches Bäderbuch. Bearbeitet Unter Mitwirkung des Kaiserlichen Gesundheitsamts. Pp. 535.
B. T. and Co. (London).
The Diagnosis and Treatment of Pulmonary Consumption. By Arthur Latham, M.A., M.D., &c., &c. Third Edition. Pp. 259. Price 5s. net.
Ulceration of the Cornea. By Angus Macnab, B.A., B.Sc., &c., &c. Illustrated. Pp. 196. Price 5s. net

REVIEWS OF BOOKS.

CANCER—A HUMAN SCOURGE(*a*).

This is the least satisfactory addition to the series of volumes forming the well-intentioned, and in many respects admirable, "New Library of Medicine," edited by Dr. C. W. Saleeby. Its title is uninforming, and its sub-title is objectionable, and, as some will doubtless aver, misleading. Mr. Childe, with a youthful optimism hardly born of experience, has undertaken the peculiarly difficult and dangerous task of writing a book for the public on "cancer." He has undoubtedly succeeded in producing a smart and readable work. Realising that "offence must come" from the issue of such a book, he boldly faces the situation, and, with courage, if not discretion, hesitates not to proclaim his gospel of hope in surgery for the cancerous. The object of the book is very simple. It is to educate the public on the necessity for early medical—or should we not say surgical?—advice. Mr. Childe's axioms are :—1. "Cancer is, in its beginnings, a local

---

(*a*) "The Control of a Scourge, or How Cancer is Curable." By Charles P. Childe, B.A., F.R.C.S., Surgeon Royal Portsmouth Hospital, Pp. 299. London: Methuen and Co. 1906. Price 7s. d.

disease, and confined at first to the part it first attacks." 2. "From its local site of origin it generally very soon disseminates itself into the system of its victim." These "facts," as he calls them, lead the author to insist that "a period exists in every cancer, longer or shorter as the case may be, when it is local, when it is operable, when it is curable." Special reference is made to mammary, uterine, oral and lingual, gastro-intestinal and cutaneous cancer, but the common occurrence of malignant disease in other parts of the body oftentimes inaccessible—if the surgeon will allow the use of such an obsolete word—seems almost to have been forgotten. We cannot but fear that the author has weakened his case by a dogmatism which must oftentimes bring disappointment. For instance, some would think that the following is at least but a partial truth:—"Cancer itself is not incurable. It becomes incurable from the simple fact that its unfortunate victims harbour and nurse their cancers till it is too late. It is not the disease which is incurable; it is the delay that makes it so." Mr. Childe is evidently not an experienced pathologist, else he would lay greater stress on the latency of malignant disease and the long-deferred appearance of localising signs in many cases of cancer of internal organs. The chapter on "Danger Signals" should enforce the author's text, "Seek medical advice without a moment's delay." Mr. Childe is candid, for he tells his reader that, "It must be frankly confessed at the outset that the cause of cancer is unknown," and he might have added that, as a consequence, the rest of his book was unavoidably little more than an uncertain groping in the dark. Mr. Childe is a bold writer, with an incisive, unconventional style, and does not hesitate to enforce his points by Scriptural allusions and slang phrases which, although jarring on hyper-sensitive susceptibilities, undoubtedly go far to grip the attention of a hustling public. The purpose of the book is excellent; the execution merits commendation, but the inherent difficulties of the subject and the situation can hardly be overcome by courage while knowledge lingers.

A STUDENT'S MANUAL OF HISTOLOGY (*a*).

A sound knowledge of histology is essential for the student. Dr. Hill's admirable manual forms a reliable guide and companion for the laboratory. Only fundamental and essential subjects are presented. The descriptions are concise and clear, and the matter is well arranged. The special feature of the work, however, is the excellent series of figures—some being coloured—which will be of the greatest service to the elementary student. Reference should also be made to the unusually detailed account of the teeth, and the illustrations of dissected skulls showing the development of the teeth are admirable. Good paper, clear printing, convenient size, and flexible covers makes this a book likely to be popular with many students.

INTERNATIONAL CLINICS. (*b*)

The present volumes of this quarterly contain, as is customary, a series of clinical lectures and original articles on therapeutics, medicine, surgery, and the various allied specialities, and number among their contributors writers of note from France and Italy, as well as American and British authors, who, naturally enough, between them have contributed the large majority of the articles. Very few, if any, of the papers can be regarded as adding much to our knowledge from a purely scientific point of view; but on the other hand many of them are excellent and practical expositions of the present state of our knowledge concerning ordinary cases such as are met with every day in general practice. The illustrations are numerous and well executed, special praise being due to the group that is included in the paper entitled "Tumours of the Mammary Gland," by Dr. Rodman, of Philadelphia, and to those that illustrate Dorland's paper on "The Female Perineum and its Rep In the therapeutical section the article of most int is that on Fournier's present treatment of syph As is well known, Professor Fournier has rece advised that mercurial courses should be give syphilitic patients not only during the first couple years after they have contracted the disease, but about the fifth and eighth years. He bases modification of his previous practice on the ana of a number of paretic cases, in which he found the first symptoms of general paralysis showed th selves most often in the sixth year after the prim chancre, and that from that year up to the twe after infection the onset of G.P.I. was more noted than during any preceding or subsequent ye The new method is designed to prevent such onset the use of mercury during those most danger periods. The present writer, Monsieur Saingery, Paris, does not believe in the syphilitic origin general paralysis, and expresses the fear that merc may, by weakening the individual's resistance, incre rather than diminish the frequency of the disea and criticises Fournier's treatment from that point view. The paper is interesting, but as his fun mental premise is, as far as we know, incorrect, attack cannot be regarded as a very serious c Another interesting paper is that by Rovighi on t "Surgical Treatment of Nephritis by Decapsulatio He has produced experimental nephritis in rabbits means of diphtheria toxin and cantharides, and cla to have cured the condition again by unilateral deco cation, while control animals, which were not opera on almost invariably died. The number of his expe ments, however, is not great enough to admit of t far-reaching conclusions that he has arrived at, does he seem to have observed the experime animals for a sufficient time after operation, to pr that the new formed capsule does not ultimate invade the kidney substance and lead to cirrho The clinical papers are too numerous to admit individual mention, but most of them well rep perusal, and as they deal with a large variety o subjects they should be of value to the general pract tioner. Dr. Abraham's paper on "The Irregu Heart," and Dr. Moffitt's on "Persistent Vomiti appear to us to be the best of them, while Ban views on "Leukæmia and Sarcomatosis" will a many in systematising their ideas on the very comp group of diseases included under that heading.

INTERNATIONAL CLINICS (*a*).

This, the last volume of the sixteenth series International Clinics, contains the usual miscella of articles on therapeutics, medicine, surgery, gyna logy, laryngology; twenty-two papers in all be included within the compass of about three hund pages. None of the papers can be regarded as ve original, but they are all without exception go clinical and practical expositions of the various subje dealt with, and as such are well calculated to pr of interest to the practising medical man, and to h him to attain to the utopian condition of being gen ally up-to-date. In the therapeutical section, t best contribution is that by Dr. Rhein, on elec therapeutics. In his paper a summary of a l important facts of the subject is to be found, a numerous practical tips are recorded, which can be found with ease elsewhere. The section on medic contains two valuable summaries, one on "Rec Progress in our Knowledge of the Adrenals," and anot on "The Physiologic Influence of Lowered Baromet Pressure." Dr. Dieulafoy, of Paris, contributes article on Syphilitis Aortitis, and a really helpful pap on "Obscure Renal Hæmaturia" is from the pen Dr. Elliot, of Chicago. In the surgical section Wallace writes on Vesical Tumours, and though he holds out hope that early cystoscopic examinations may in the future lead to better results from operat

(*a*) "A Manual of Normal Histology and Organography." By Charles Hill, Ph.D., M.D., Assistant Professor of Histology and Embryology at the North-Western University Medical School, Chicago. Pp. 463, with 312 figures. Philadelphia and London: W. B. Saunders Company. 1906. Price not given.

(*b*) "International Clinics." Vols. II. and III. Sixteenth Series., Philadelphia and London: J. B. Lippincott Company. 1906.

(*a*) "International Clinics." Vol. IV. Sixteenth Series. Edited by A. O. J. Kelly, M.D., Philadelphia. Philadelphia London: J. B. Lippincott Co.

he is compelled to admit that at present the prognosis is undoubtedly bad. Some of his figures are interesting—thus he points out that the operative mortality in cases of benign tumours is 17 per cent., and in malignant cases 27 per cent.; in benign cases rapid recurrence was met with in 20.5 per cent. of cases, and in 26.8 per cent. of the malignant cases; while palliative treatment was adopted in 89 patients and few of these lived longer than six months. This paper is well worthy of study. Almost all the papers in the surgical and gynæcological sections are profusely and well illustrated, as is the rule in this quarterly journal. The illustrations alone, indeed, make the volume an object to covet.

A SYSTEM OF GYNÆCOLOGY. (*a*)

In dealing with a book which comprises articles from the pens of so many distinguished gynæcologists, we have many difficulties to contend with. In the first place, gynæcology, unlike medicine, does not lend itself to a great degree of sub-division, with the result that many of the articles overlap each other, and we find statements made in one which are practically contradicted in another. This must surely prove a deterrent to all but specialists in gynæcology, who, devoting themselves to this branch of the profession, usually possess the full works of many authors. So we are almost tempted to ask the question, "Cui bono?" with regard to the work before us.

The book opens with a very interesting chapter upon the development of modern gynæcology, and can only make the reader stand amazed at the giant strides this subject has made within recent years. The section devoted to the anatomy of the pelvis is clearly and concisely written, the illustrations being good and explanatory. The various methods of pelvic examination are fully described and stress is laid upon that most important one of all—the recto-vagino-abdominal—a method which receives as a rule too slight recognition at the hands of many writers.

Under the heading of "Disorders of Menstruation," the hæmorrhages are carefully considered; but there is no mention made of the treatment by atmocausis in these cases in which it has been of late considered suitable. Later in the book this treatment is briefly outlined, but it is curious to note the difference in the method of application between the writer and Dr. Ludwig Pincus. The latter, in his recently published work on the subject, points out that anæsthesia is not advisable during the operation, but in the article, "Atmocausis," we find it stated that anæsthesia should be pushed to the full surgical degree. Again, we learn from Dr. Pincus that whenever possible, the operation should never follow curettage, but here we find it recommended to curette the uterus previously, if we find it necessary; no indications are given. It would be interesting to know upon what these differences are based.

Schultze's diagrams illustrate the bi-manual method of reposing a retro-flexed uterus, a tribute to that great authority which is paid by nearly every writer on the subject. Fig. 65 compares very unfavourably with them, being wretchedly drawn and conveying quite a wrong impression as to the position of the uterus maintained by a pessary. In addition to the bi-manual, reposition by means of the sound is described and figured, no mention being made of that simpler and far less dangerous procedure of replacing a retro-verted uterus by means of a bullet forceps on the anterior lip of the cervix and a finger introduced into either the rectum or vagina.

Having replaced the uterus, we are told that should the vaginal pessary prove an insufficient means of support, by the cautious introduction of an intra-uterine stem benefit will be obtained. Has the stem pessary any place in modern gynæcology?

Many of the articles are fully written and well illustrated, the one on "Chorionepithelioma" being of great interest, and the illustrations of the pathological sections clearly reproduced. In spite of the fact that it used to be performed ten years ago, it is doubtful if any advantage is to be gained by the description of the supra-vaginal amputation of the uterus with extra-peritoneal treatment of the stump.

The volume is well bound and printed, and of a very convenient size, and, needless to say, contains much valuable information upon recent developments in gynæcology.

WORKS ON REFRACTION OF THE EYE.

We welcome a new edition, the seventh, of Morton's excellent little manual (*a*). The popularity which the work has gained is well deserved, inasmuch as it places before the student in refraction all the essentials of the subject, in plain and concise terms, without the padding of unnecessary details. In this new edition the work has been revised and largely rewritten, while a useful chapter has been added dealing with the applicability of prisms to the treatment of refraction cases.

Mr. Hartridge has carefully revised his work in the new edition (*b*), which has become so popular. But little need be said in the way of criticism of a manual of which twenty-eight thousand copies have been sold. The fact of its popularity speaks for itself for, despite the large number of works published upon the subject of refraction, this volume still maintains the position it established as long ago as 1884. We congratulate the author upon his success—a success, which, nevertheless, is deserved—inasmuch as his book is well written, plainly expressed, and deals in an eminently practical manner with the mass of detail inseparable from the work of a refractionist.

PULMONARY PHTHISIS (*c*).

The early diagnosis and prompt treatment of incipient phthisis are so important that we welcome every attempt to facilitate recognition of what may, for clinical purposes, be called the præ-tuberculous stage of the disease. In the sense in which we use this term we mean merely that the tuberculous lesions, though possibly present, are not as yet manifest. The author's attitude is in favour of erring on the right side and instituting appropriate treatment whenever we are in presence of a departure from health not explained by obvious disease. The author devotes much attention to the question of prognosis in phthisis, and some useful hints are given as to the interpretation to be placed on physical signs for this purpose. With regard to the treatment of phthisis the author, of course, has nothing very new to say. He, however, gives good practical advice on general hygiene and medicinal measures, but he speaks hesitatingly about the employment of the various tuberculins and serums—not without just cause. His remarks on the application of the opsonic index are rather scanty considering the importance of this discovery. Is he not in error in conveying the idea that it is possible by injection of tuberculin, controlled by the opsonic index, to redetermine a "high and continuous level of tissue resistance"? There is now sufficient material on hand to justify a more elaborate description of the method and its bearings. It is, however, a sound essay, which will be found of service by general practitioners who have to bear the brunt of the battle against tuberculosis, and need every assistance in so doing that their experienced brethren can afford.

WEEKLY SUMMARY OF MEDICAL LITERATURE, ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT PATHOLOGICAL LITERATURE.

Adenoma of Langerhan's Islands. — Helmholz points out (*Johns Hopkins Hospital Bulletin*, May, 1907) that tumours of the pancreas of epithelial origin may arise: (1) from the duct epithelium, (2) from the pancreatic cells proper, and (3) from the cells of the Langerhan's islands. Tumours arising from the first two sources are common, but those from the third source are rare. The present specimen was found by chance, in a block of tissue removed for microscopical examination. It measured 5 by 3 by 5 mm., and was visible in section as a dull grey finely granular area, sharply circumscribed on all sides by a thin capsule. The structure of the tumour presented a stroma of connective tissue carrying blood vessels; the connective tissue network presented large delicate meshes in which lay solid hollowed out anastomosing masses of epithelial cells. The cells are polyhedral in outline, with coarsely granular protoplasm presenting clearly defined nuclei. The origin of the tumour from Langerhan's islets was suggested by the following points: (1) The anastomosing arrangement of the acini; (2) the intimate relation of the capillaries to the epithelium; (3) the general characters of the tumour cells which closely resemble those of the cells in the pancreatic cell islets. M.

Suture of Blood Vessels and Transplantation of Organs. — Watts contributes an important paper on the above subject to the *Johns Hopkins Hospital Bulletin* for May, 1907. After an exhaustive historical survey of the subject of blood vessel suturing, he reports the results he has himself obtained. He cut and then sutured the common carotid artery thirteen times, and in each case with a successful result; thirteen sutures of the external jugular vein gave ten successes, while two sutures of the femoral artery were both failures. Microscopical examination of the arterial sutures from 28-82 days after operation shows a gradual restoration of the entire arterial wall, except the elastic lamina. The common carotid artery was sutured to the external jugular vein four times, all being successful. Examination of the veins from 1-3 months later showed dilatation of these vessels with thickening of their walls and increase of elastic tissue in places. In four animals a lateral anastomosis of the femoral artery and vein was made; but in only one animal did the opening remain patent. In one other a thrill and murmur persisted for four weeks, and then disappeared, due, as the autopsy showed, to healing of the opening while both vessels remained patent. Excision and replantation of a portion of the femoral artery was done once but failed owing to thrombosis; on the other hand, a section of the external jugular vein was transplanted into the common carotid artery with complete success. Transplantation of the thyroid gland was done six times, but in no case successfully. The writer is, however, inclined to attribute this want of success to the small size of the inferior thyroid vein, and to the fact that the work was undertaken before he had himself gained skill with vascular suturing. He claims that his results show conclusively that completely divided vessels can be sutured with almost uniform success, when the aseptic technic is good. The intima can be included in the suture with impunity, the application of the suture being thus greatly facilitated. M.

Bier's Treatment by Hyperæmia.—Barcroft (*Edinburgh Medical Journal*, June, 1907) publishes a much needed description of the treatment of acute inflammatory disorders by Bier's method of inducing hyperæmia. Hitherto references to the subject in English have been few and partial. As regards theory, Bi treatment starts from two obvious physiological fa (1) Every organ during functional activity is hy æmic. (2) All growth and repair is evidenced hyperæmia, which is in proportion to the energ the process. As regards practice, Bier can point wide experience of several years' duration in sup of his method. There are few acute inflamma disorders which he has not treated successf Where possible, active hyperæmia is induced; commonly one has to be content with passive hy æmia. The former may be induced by stimulati the part by rubefacients, by massage, by electri or by heat. Heat is the method of choice, and attains his end by means of the hot-air bath. mode of treatment has the additional advantage it gives great relief to pain. Passive hyperæmia the other hand, is produced over small areas by cupping-glass, over larger areas by the suction ap ratus, and in the limbs by means of the elastic band In acute inflammations he applies the chosen ment for some twenty hours of the twenty-four intervening periods being used to reduce the œde Barcroft gives details of the methods of applica of the treatment to various clinical conditions. R

Carcinoma in Animals. — Loeb (*University Pennsylvania Medical Bulletin*, March-April, publishes an account of his recent investigation the endemic occurrence of carcinoma in animals on the inoculability of tumours. Some of his c clusions may be summarised as follows: (1) Heredita transmission of certain predisposing conditions fr parents to offspring is one of the factors causing demic occurrence of cancer among animals. Various kinds of tumours grow better when inocu into the animal in which the tumour had deve originally, or into an animal affected with the s kind of tumour, than when inoculated into animals of the same species. (3) There is no paral between the tendency of tumours to become ma and their inoculability. (4) Metastases into lymph glands were never found. (5) Microscopic stases could be found in the lung in a certain nu of cases when macroscopically no metastases evident. R

Splenomegalic Polycythæmia. — Saundby *Med. Journ.*, May 18th, 1907) reports two cas this rare condition, collects other reported cases puts forward a suggestion as to its pathology. discusses the question whether the polycythæmi apparent or real, and inclines to the opinion that only apparent. He quotes the observation of gra that when the vasomotor nerves are stimulate cold, the specific gravity of the blood is incre Under other conditions of high arterial tension number of corpuscles per cubic millimetre of the is increased. These changes are of course due to fact that with a general contraction of the ve walls, and a consequent decrease of their capa fluid is squeezed in excess into the tissues, leavi fluid richer in corpuscles in the vessels. Saun also adduces arguments to show that the diseas not a primary disease of the bone marrow or sple He believes then that the condition is due to narrow of the middle-sized arteries and arterioles, due in turn to a vasomotor spasm which has become org by thickening of the coats of the vessels. The va motor derangement may be part of a general neur thenia, caused at any rate in some cases by an atta of influenza. The resultant engagement of the ven and capillary systems also manifests itself in perplasia of the hair and spleen, while other symp- ms of the neurasthenia are muscular weakness, ss of knee-jerks, and mental impairment, such as owsiness, apathy and loss of memory. R.

The Physiology of the Parathyroids in Man.—orsyth (*Brit. Med. Journ.*, May 18th, 1907) pub- shes the results of an investigation into the structure d secretion of the parathyroid glands in man. He ncludes: (1) The parathyroid gland, like other ands, presents histological variations of activity d rest. The so-called oxyphil cells are the cells stended with granular secretion, and the so-called incipal cells represent the exhausted stage. Inter- ediate forms are common. (2) The secretion of the lls is extended into the surrounding lymphatic spaces, d the product of many cells may run together to rm a drop. The secretion is gradually drained away the lymphatics. (3) The secretion of the para- yroid, both in its physical and micro-chemical aracters, is indistinguishable from the colloid of e thyroid. (4) During the first few months of life e parathyroid glands show few, if any, signs of tivity. By the end of the third month colloid cretion is usually found. R.

The Blood in Rheumatoid Arthritis. — Bull- ore and Waterhouse (*Edin. Med. Journ.*, June, 907) publishes the results of an investigation into e condition of the blood in a series of forty-two ases of rheumatoid arthritis. They remark that ey have been unable to find any detailed description ublished hitherto. (*a*) *Hæmoglobin.* In only one ase was the percentage of hæmoglobin 100. In eight, was between 90 and 100, in twelve between 80 and 0, in eleven between 70 and 80, in four between 0 and 70, and in one 30. (*b*) *Red blood cells.* In ll but nine cases the number of red cells was below ,000,000 per cmm., in twenty it was between 4,000,000 nd 5,000,000, in ten between 3,000,000 and 4,000,000, nd in one only 2,890,000. The microscopical appear- nces were those of a secondary anæmia of greater r lesser degree. The colour index varied from 0.72 slightly over normal. The constancy in the number f white corpuscles was remarkable; in all but six stances they were between 5,000 and 10,000. Except one case, the differential leucocyte count showed hysiological proportions between the various forms. yclocytes were present in a few cases. R.

Ovarian Grafting.—Carmichael (*Journal of Ob- tetrics and Gynæcology of the British Empire*, March, 907) has added some facts to our knowledge of the ossibility of grafting ovarian tissue. He performed number of experiments on rabbits, and in fifteen out f twenty-one attempts some measure of success was ttained. In the majority of cases (about 80 per cent.) here was partial degeneration of the transplanted issue, the degeneration being either fibrous or cystic. he Granpian follicles and ova persisted and matured or some months after grafting, but ultimately tended o become cystic. The germinal epithelium persisted a small proportion of the cases. As regards the ossibility of grafting in the human subject, he oncludes: (1) It is unlikely that the whole human vary can be transplanted with success. (2) Part f the ovary may ovulate and preserve its function f internal secretion. (3) Grafting of a part, *e.g.*, f the cortex of the organ, is more likely to succeed han of the whole. R.

Action of Wine on the Typhoid Bacillus.—The ossibility of the carriage of typhoid infection by ther means than drinking water should not be over- ooked. In countries where cheap wine is a common rticle of diet, it is of importance to know whether ine may be the infected vehicle. Labrayes and arcaudin have therefore done a valuable piece f work in testing the bactericidal powers of various ines toward the typhoid bacillus (*Annales de l'In- titut Pasteur*, April 25th, 1907). They find that ines which have been long bottled are sterile, while red wines from the wood have a rich bacterial flora. Pure wines exercise a powerful bactericidal action on the typhoid bacillus, but this action varies in intensity with the nature and quality of the wines. White wines were found to be more active than red, and sour wines than sweet. The proportion of alcohol present has little effect on the bactericidal power, but various other bodies—glycerin, ethers, amylic alcohol—in all probability are of greater importance. Dilution weakens considerably the antiseptic action of wine. R.

Pathology of Chronic Metritis.—Chronic metritis has recently been the subject of much investigation. Donald and Shaw publish (*Journal Obstetrics and Gynæcology of the British Empire*, February, 1907) separate papers on the subject. Donald devotes himself chiefly to the clinical aspects of the condition, and Shaw to the pathological. The latter gives some good micro-photographs, and comes to the following conclusions: (1) Chronic metritis is a simple hypertrophy of the meso-metrium, and is not a connective tissue hyperplasia. By "meso-metrium" is meant the muscular coat of the uterus. The word is ambiguous and should be avoided. The proportion of connective tissue varies considerably, but many normal uteri possess as much or more. The vessel changes are variable, and similar affections are found in normal uteri. There is no evidence of active inflammation, as shown by small celled infiltration or cicatricial tissue. (2) Chronic metritis is a progressive affection. (3) It is never primary, but usually consequent on a chronic endo-metritis. It may however, be due to other uterine disease leading to increased uterine contraction or vascularity, *e.g.*, fibroids, tubo-ovarian inflammation, carcinoma, prolapse. R.

A Rare Tumour of the Vagina.—Doran (*Journal of Obstetrics and Gynæcology of the British Empire*, June, 1907) reports an interesting case of hypernephroma with a secondary growth in the vagina. Incidentally he analyses the literature of tumours of the vagina. In the case reported the right kidney was the seat of a tumour, 4½ inches by 2½ inches by 2¼ inches, which microscopically showed resemblance to the zona fasciculata of the adamal body; the growth was separated from the cortex of the kidney by a thin but quite distinct sheet of fibrous tissue. The vaginal growth was polypoid in character, and was at first taken for a sarcoma. Microscopically it showed close resemblance to the growth in the kidney. Doran emphasises the necessity of looking for primary facies in all cases of malignant tumour of the vagina. R.

Society of Apothecaries of London.

The Society of Apothecaries of London Bill was read a third time in the House of Commons last week, having previously passed through all its stages in the House of Lords; it now requires only the Royal Assent to make it law. Under the first Act of Parliament, the Apothecaries Act, 1815, the Society was enabled to grant to persons passing the necessary examination a certificate of their qualification to practise as an apothecary. The designation of such person was "Licentiate of the Society of Apothecaries." In 1887, in accordance with the Medical Act of the previous year, candidates for the Society's diploma were required to pass an examination, not only in medicine, but in surgery and midwifery, though no alteration was made in the title. The new Bill is designed to remedy this omission, and provide that all persons who have passed the examination since 1887, and shall hereafter pass it, shall be styled "Licentiates in Medicine and Surgery of the Society of Apothecaries, London," thus clearly indicating that the owner of the diploma possesses a qualification both in medicine and in surgery. The Bill also authorises the General Medical Council to enter the new title upon the Medical Register.

MEDICAL NEWS IN BRIEF.

Royal College of Surgeons in Ireland.

AT a meeting of the College, held on Monday, June 3rd, the following were elected president, vice-president and Council:—President, Henry R. Swanzy; vice-president, John Lentaigne; hon. secretary, Sir Charles A. Cameron; Council—William Stoker, Sir Charles A. Cameron, John B. Story, Sir Charles B. Ball, Sir Thomas Myles, Sir Arthur Chance, Richard D. Purefoy, Sir Lambert H. Ormsby, Henry G. Sherlock, R. Bolton M'Causland, John S. M'Ardle, Robert H. Woods, R. Lane-Joynt, Thomas Donnelly, William Taylor, Edward H. Taylor, R. Charles B, Maunsell, Wm. Ireland Wheeler and D. Edgar Flinn.

Royal Medical Benevolent Fund.

LAST week the annual meeting of the Royal Medical Benevolent Fund Society of Ireland was held in the College of Physicians, Dublin. The chair was occupied by the President of the Royal College of Physicians of Ireland.

During the present year eleven applications for grants were considered in anticipation of the regular annual distribution—five coming from new applicants. Of the eleven applications one was refused, two were postponed to the annual distribution, and the remaining eight being all pressing, grants, amounting to £79, were made. The total amount of the grants recommended since last distribution is £1,114. The total number of applicants considered during the year was eighty-four. Of these seventy-five were from widows of medical men; five from, or on behalf of, their orphans; and four from medical men themselves. The number of applicants this year has been even larger than usual, and the amount given in grants has strained the resources of the Society to the utmost, though the aid given to many of the recipients has fallen far short of their claims and of their urgent necessities.

Deputy Surgeon-General C. Joynt, M.D., read the treasurer's report. It stated: During the year 1906–7 the grants awarded by the Central Committee amounted to £1,097 10s., or £24 less than in the preceding year. The grants awarded for the last eight years averaged £1,182. Dividends on stock realised £690 3s. 2d., including a refund of £33 15s. 5d. income-tax. This shows an increase of £11 2s. 3d. The amount paid through the Central Treasurer was £221 19s., as compared with £196 6s. in the preceding year. Miscellaneous receipts realised £15 14s 6d. The subscriptions forwarded by the Branch Treasurers amounted to £343 0s. 6d., as compared with £323 4s. 8d. the preceding year. The Belfast and County Antrim Branch contributed £149 14s. (including £7 18s. received late for audit the preceding year), an advance on any former year. The County Armagh Branch contributed £22 16s. 6d., the next largest contribution from any of the County Branches. Of the £343 received from County Branches, £154 should have appeared in last year's account, but was only received after that account was audited.

Among those who took part in the proceedings were the President of the Royal College of Physicians, Sir John Moore, Drs. Andrew Horne, Edward Taylor, Travers Smith, Donneley, Purser, Craig, and Benson.

Irish Medical Association.

THE annual meeting of the Irish Medical Association was held on Wednesday, the 5th inst., at Portrush, the President, Mr. J. S. McArdle, in the chair; there was a large attendance of members.

The Secretary submitted the annual report, in which particulars were given of the various legal cases undertaken during the year.

The question of the appointment of a *locum tenens* for a medical officer going on vacation had been considered, and cases referred to in which conditions were laid down by the Boards of Guardians mak it difficult, if not impossible, for the medical offic to go on vacation. The Local Government Boa expressed their sympathy with the doctors in t matter, and stated that circular letters had been issu to Boards of Guardians advising them to appoint substitutes, wherever possible, those recommended the medical officer.

In the matter of remuneration offered by the Po master-General for attendance on rural post-offi officials, letters were addressed to the British Post Medical Association, and also to the Postmaste General. The British Postal Medical Associati replied that they did not consider it necessary to ta any action at present. The Postmaster-General wro stating that in his opinion the capitation fee of 8s. allowed to medical officers to the Post Office is adequa in amount, and that it compared favourably w that accorded to the medical officers of friend societies and to police surgeons; that with regard the age limit, while the efficiency of medical offic over sixty years of age is reviewed annually, no medic officer is called upon to resign until he is 90 years age. The Association had lost no opportunity pressing home the need of superannuation and, a temporary expedient, have endeavoured to get secti 118 of the Local Government Act, 1898, amended, as to include all existing officers.

The records of the Re-organisation Committee, t Finance Committee, and the statement of audit accounts were considered.

The election of officers, which was by ballot result as follows:—President—Dr. John S. McArdle. Merrion Square, Dublin (re-elected); Vice-Presiden —Ulster, Dr. Leonard Kidd, West Bridg Enniskillen; Munster, Dr. W. MacSweeny, Pa Place, Killarney; Leinster, Dr. F. W. Kidd, 17, Low Fitzwilliam Street, Dublin; Connaught, Dr. R. Kinkead, Foster House, Galway; Hon. Sec., Dr. Donnelly, 14, Rutland Square, Dublin; Hon. Treasur Dr. W. J. Thompson, 59, Fitzwilliam Square, Dublin.

The President then delivered his address, and variou matters of business were discussed.

In the evening a dinner was held at the Norther Counties Hotel.

St. Thomas's Hospital.—House Appointments.

THE following gentlemen were selected as Hou Officers for the ensuing term:—Casualty Officer (Senior) A. B. Howitt, M.A., M.B., B.C.Cantab (Junior) W. O. Sankey, M.B., B.S.Lond. Reside House Physicians: E. V. Dunkley, M.B., B.S.Lon (extension); H. A. Philpot, B.A.Oxon, M.R.C.S. L.R.C.P. (extension); C. E. Whitehead, B.A.Canta M.R.C.S., L.R.C.P.; H. G. Bennett, M.B., B.S Lond. House Physicians to Out-Patients: G. G Butler, B.A.Cantab., M.R.C.S., L.R.C.P. (extension S. L. Walker, B.A., B.C.Cantab. (extension); W. H. R Sutton, B.A., B.C.Cantab.; S. Churchill, B.A., M.B. B.C. Cantab. Resident House Surgeons: C. M. Page M.B., B.S.Lond. (extension); S. G. MacDonald M.A., M.B., B.C.Cantab. (extension); H. B. White-house, M.B., B.S., Lond. (extension); R. L. Gamlen B.A.Cantab., M.R.C.S., L.R.C.P. (extension). Hou Surgeons to Out-Patients: H. J. Nightingale, M.B B.S.Lond. (extension); H. R. Unwin, M.B., B.C Cantab. (extension); G. M. Huggins, M.R.C.S L.R.C.P. (extension); F. M. Neild, M.B., B.S.Lon (extension). Obstetric House Physicians: (Senio A. C. D. Firth, M.A.Cantab., M.R.C.S., L.R.C.P (Junior) F. S. Hewett, B.A., M.B., B.C.Canta Ophthalmic House Surgeons: (Senior) W. C. A. War M.R.C.S., L.R.C.P. (extension), (Junior) A. S Burgess, M.A.Cantab., M.R.C.S., L.R.C.P.(extension

Throat: W. R. Bristow, M.R.C.S., L.R.C.P. (extension); R. E. Todd, M.B., B.S.Lond. Skin: A. J. S. Pinchin, M.B., B.S. Lond.; E. A. Sparrow, B.A.,Cantab., M.R.C.S., L.R.C.P. Ear: A. J. S. Pinchin, M.B., B.S. Lond; H. E. T. Dawes, B.A. Cantab., M.R.C.S., L.R.C.P. Children's Surgical: H. H. Carleton, B.A., M.B., B.Ch.Oxon. (extension); R. E. Todd, M.B., B.S.Lond. Electrical Dept. and X-Ray Dept.: A. J. H. Iles, M.R.C.S., L.R.C.P.

Opening of Cossham Memorial Hospital.

THE opening of the Cossham Memorial Hospital on June 1st excited considerable interest at Kingswood and Two-Mile Hill. Mr. Handel Cossham left the residue of his estate for this purpose, and his trustees eventually found themselves in possesion of about £120,000. They were thus in the fortunate position of being able to spend £30,000 on building and equipping a new hospital with fifty beds, and investing the balance as an endowment to enable the work to be maintained. A fine site on Lodge Hill was obtained for the hospital, and this being in Stapleton parish the new institution, since erected from the designs of Mr. Bligh Bond, stands within the boundary of the city of Bristol. At the opening ceremony Mr. W. Butler presided, and there were present the Lord Mayor and Lady Mayoress, the Right Hon. Augustine Birrell, the High Sheriff (Mr. Henry Daniel), the Right Hon. Lewis Fry, and many other well-known Bristol people.

City of London Hospital Dinner.

ALDERMAN AND SHERIFF CROSBY, M.D., in the absence of the Lord Mayor through indisposition, presided on June 4th at the festival dinner of the City of London Hospital for Diseases of the Chest, Victoria Park, and read the following telegram from the Duke of Connaught, president of the Hospital: "The Duke of Connaught sends you his best wishes, and trusts every success will attend the festival dinner this evening." In proposing the toast of the evening the Chairman said that large numbers of poor patients awaited admission, and if the thirty-two beds, now closed for want of funds, could be re-opened, two hundred more in-patients could be admitted annually.

The Secretary announced subscriptions to the amount of £2,415, which included ten guineas from his Excellency Wang Tahsieh, the Chinese Minister, who was present. The announcement of his gift was loudly cheered.

Brompton Consumption Hospital.

THE Lord Mayor presided, on May 31st, at the Mansion House at a meeting called to further the movement to secure an increased income for the Hospital for Consumption at Brompton.

His Lordship said that the institution was founded in 1841, and they now had a convalescent home at Frimley. When they reflected on what a terrible scourge consumption was they must appreciate the good work done by the hospital.

The Earl of Derby, in advocating the claims of the hospital, said that a letter which Lord Cheylesmore and himself sent out had been erroneously construed in some quarters as an attack on the King's Hospital Fund. What they desired to show was that through no fault of theirs the contributions to the hospital had fallen short, but there was not the slightest intention to reflect on the King's fund. In the treatment of consumption they now found that a great deal might be done in anticipating infection rather than in dealing with it when it occurred. Their treatment of patients at the Frimley Sanatorium, good as it was, had added to the calls on their funds. He believed it to be a source of England's strength that our charities were maintained as they were to-day.

Lord Cheylesmore said he endorsed the statement by Lord Derby that their appeal on behalf of Brompton was in no way intended as an attack on the King's Fund, or even as a criticism of the administration of that fund. They especially required funds for the support of their sanatorium, otherwise beds would have to be closed. As a former mayor of an important borough he must call attention to the way hospitals were rated. For instance, Brompton Hospital was situate in the boroughs of Kensington and Chelsea, and for each bed in the institution they had to pay £3 13s. 10d. in rates and taxes, which was an excessive amount. Then at Frimley, where the sanatorium was, £4 12s. 11d. went in rates and taxes for each bed. Lord Cheylesmore mentioned that ninety-three persons out of one hundred and ten who were treated in the sanatorium were now engaged in their ordinary pursuits. Regarding the suggestion that the hospital should be removed to the country, he pointed out that the eminent medical men who now gave freely their time and skill could not do so if the institution was taken further afield.

Sir R. Douglas Powell and other gentlemen also delivered addresses in support of the movement.

Guy's Hospital and the University of London.

THE following letter has been addressed by the treasurer of Guy's Hospital to the principal of the University of London:—

"Guy's Hospital, S.E., May 10th, 1907.

"Dear Sir,—As treasurer of Guy's Hospital I have to bring to your notice the following resolution, passed at a school meeting of the 7th inst., and approved by me:—'That, in view of the resolution of June, 1905, that the Medical School of Guy's Hospital is not committed to any particular line of action with regard to the concentration of preliminary and intermediate studies, the school now desires the treasurer to inform the Senate of the University of London that it is of the opinion that the proposed scheme of three centres for the teaching of such subjects at University College, King's College, and South Kensington, and the institution of internal examinations at these centres, would not be to the advantage of medical education in London, and that it does not propose to abandon the teaching of the preliminary and intermediate subjects under these circumstances.' I desire to add that this decision must not be construed as adverse to the principle of the concentration of the preliminary and intermediate medical studies in the University, but solely as directed against the particular proposals for concentration indicated in the resolution.—I am, dear Sir, yours faithfully,

H. COSMO O. BONSOR, Treasurer."

The Year's Sanitary Work at the Port of Manchester.

A FAVOURABLE report has just been presented by Mr. W. F. Dearden, the medical officer of health, to the members of the Port of Manchester Sanitary Authority. The total number of cases of sickness reported during the year was 174, the greatest annual number reported since the formation of the Port Sanitary Authority—owing, it is believed, to the arrival of ships from greater distances than formerly and to the fact that many of them have been heavier vessels.

Infant Mortality.

SPEAKING at the seventh annual general meeting of Virol, Limited, held at the Holborn Restaurant on Friday last, Mr. B. S. Straus, M.P., referred to the high rate of infant mortality in the country, and quoted from a statistical study of the question by Dr. Newsholme, Medical Officer of Health for Brighton, that out of every thousand born in England and Wales during the years 1901-4 only 141 succeeded in reaching their first anniversary, and that this rate of infant mortality had remained stationary during the last fifty years, although the death rate between the ages of 5 and 25 had been reduced by 50 per cent. in the same time. During the same period the birth rate has fallen 17 per cent. The causes of death enumerated by the Registrar-General as accountable for this appalling rate of mortality were, he remarked, the very conditions that the use of Virol was calculated to prevent. That this fact was appreciated by the medical profession was shown by its greatly increased use in hospitals and nursing homes.

NOTICES TO CORRESPONDENTS, &c.

☞ **Correspondents** requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Reprints.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

Original Articles or Letters intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessary for publication but as evidence of identity.

Concha.—The treatment of buzzing in the ears, after physical methods have failed, is a disheartening business truly. Have you tried valerianate of diethylamine (so-called valyl)? Knoff prescribes it in daily doses of 3 to 9 capsules of 125 centigrammes each. We have no experience of it ourselves.

ADDITIONS TO THE MEDICAL REGISTER IN 1906.

We are informed by the Registrar of the General Medical Council that the actual numbers of new names added last year were: In England 612, in Scotland 415, in Ireland 170, making a total of 1,197.

Dr. L. S. R.—Mrs. Honor Coleman, who resides in a cottage at Cleeve, Somerset, is generally considered the oldest woman in England. She has recently attained the remarkable age of 107, with her faculties only slightly impaired. Her mother was a centenarian, her grandmother lived to be 101, while her daughter, who lives in the same cottage, is nearly 80.

Thix.—Mr. Halliwell Sutcliffe writes to warn editors, authors, and doctors, both in London and the provinces, against "a remarkably clever and unscrupulous scoundrel who is going about collecting charity on false pretences. I sent him money two years ago, when he wrote to me from a hospital, under the plea of destitution and of the profession we shared in common. Later he called on me, and my suspicions were aroused. Since then, I find, he has been assuming my name whenever he thought it safe. Heart failure, artificially produced, is his favourite method of admission to hospitals, where he usually contrives to enlist the sympathy of those who come in touch with him. Then he borrows money from the matron, nurses, or medical staff."

Meetings of the Societies. Lectures, &c.

Wednesday, June 12th.

Dermatological Society of London (11 Chandos Street, Cavendish Square, W.).—4.30 p.m.: Special General Meeting for the purpose of dissolving the Society and Merging it into the Royal Society of Medicine.

Medical Graduates' College and Polyclinic (22 Chenies Street, W.C.).—4 p.m.: Mr. C. Ryall: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Mr. L. Cheatle: Paget's Disease of the Nipple and its treatment (with lantern slides).

Thursday, June 13th.

Ophthalmological Society of the United Kingdom (11 Chandos Street, Cavendish Square, W.).—8 p.m.: Card Specimens, 8.30 p.m.: Papers:—Mr. Nettleship: A History of Night Blindness in Nine Consecutive Generations.—Mr. L. Werner: A Peculiar Case of Subretinal Cysticercus.—Mr. A. L. Whitehead: (1) A Metastatic Tumour of the Choroid; (2) Multiple Cysts of Retina.

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Gynæcological Operations (Dr. Giles). Cliniques:—Medical Out-patient (Dr. Whiting), Surgical Out-patient (Mr. Carson). 3 p.m.: Medical In-patient (Dr. Chappel).

Hospital for Sick Children (Great Ormond Street, W.C.).—4 p.m.: Lecture:—Dr. Voelcker: Enlarged Abdomens.

Friday, June 14th.

Ophthalmological Society of the United Kingdom (11 Chandos Street, Cavendish Square, W.).—6 p.m.: Bowman Lecture: Prof. Sattler: The Pathology and Treatment of Myopia.

Medical Graduates' College and Polyclinic (22 Chenies Street, W.C.).—4 p.m.: Mr. C. A. Parker: Clinique. (Throat.)

Saturday,, June 15th.

Society for the Study of Disease in Children (County Hospital, Bedford).—3 p.m.: Discussion on Acute Rheumatism (opened by Dr. C. O. Hawthorne). Papers by Dr. E. Cautley and Mr. Tubby.

Monday, June 24th.

Odontological Society of Great Britain (20 Hanover Square, W.).—8 p.m.: Casual Communication:—Mr. Montagu F. Hopson, L.D.S.Eng., on "An Inverted Mandibular Third Molar."

Vacancies.

Abbeyleit Union.—Medical Officer. Salary £110 per annum: also to act as Medical Officer for Health at a salary of £20 per annum. Immediate application to James Finnegan, Clerk of Union. (See advt.)

Glamorgan County Asylum, Bridgend.—Junior Assistant Medical Officer. Salary £150 per year, with board, apartments, attendance, and washing. Applications to the Medical Superintendent.

Canterbury City Asylum.—Assistant Medical Officer. Salary £140 per annum, with furnished apartments, board, and laundry. Applications to the Medical Superintendent.

Oldham Union.—Resident Medical Officer. Salary £150 per annum, together with furnished residence, coal, gas, rations, washing, and attendance. Applications to Horace A. Quarmby, Clerk to the Guardians, Union Clerk's Office, Rochdale Road, Oldham.

Newcastle-upon-Tyne.—Assistant Medical Officer of Health, etc. Salary of £300 per annum, with board, lodging, etc. Applications to the Medical Officer of Health, Town Hall, Newcastle-upon-Tyne.

Egypt.—Sub-Inspector of Ophthalmic Hospitals. Salary £500 a year, with two months' salary in lieu of travelling expenses to and from England. Applications to the Director-General, Department Public Health, Cairo.

The Hospital for Sick Children, Great Ormond Street, London, W.C.—Anæsthetist. Applications to the Secretary.

West Bromwich District Hospital.—Senior House Surgeon. Salary £110 per annum, with board, residence, and laundry. Applications to T. Foley Bache, Esq., Churchill House, West Bromwich.

Rotherham Hospital and Dispensary.—Senior House Surgeon. Salary £110 per annum, with rooms, commons, and washing. Applications to the Secretary, H. Kelson, Masonic Buildings, High Street, Rotherham.

London County Asylum, Bexley, Kent.—Junior Assistant Medical Officer. Salary £150 per year, with board, furnished apartments and washing. Applications to H. F. Keene, Clerk to the Asylums Committee, Asylums Committee Office, 6 Waterloo Place, S.W.

Appointments.

Coutie, W. H., M.B., Ch.M.Melb., Medical Officer to the Callan Park Hospital, Balmain, New South Wales

Hayward, W. T., M.R.C.S., L.K.Q.C.P.Irel., Member of the Board of Management of the Adelaide Hospital, Australia.

Hill, A. W., M.D.Brux., Member of the Board of Management of the Adelaide Hospital, Australia.

Hodgson, George James, L.R.C.S., L.K.Q.C.P.Irel., Member of the Medical Board of Victoria, Australia.

Melville, Stanley, M.D.Brux., M.R.C.S., L.R.C.P.Lond., Clinical Assistant to the Chelsea Hospital for Women.

Mort, George Cecil, M.B., Ch.B.Vict., Resident Medical Officer at the Handel Cossham Memorial Hospital, Kingswood, near Bristol.

Murphy, Thomas, M.D., M.S.Melb., Surgeon to the Out-patients at St. Vincent's Hospital and Honorary Surgeon to In-patients in the Gynæcological Department, Victoria, Australia.

Purdy, J. S., M.D., C.M.Aber., D.P.H.Camb., District Health Officer, Auckland, New Zealand.

Rogers, R. S., M.D., Ch.M.Edin. and Adel., Member of the Board of Management of the Adelaide Hospital, Australia.

Wright, Garnett, M.B., Ch.B.Edin., F.R.C.S.Eng., Honorary Surgeon to the Ancoats Hospital, Manchester.

Dawson, George W., F.R.C.S.I., D.P.H., Surgeon to St. John's Hospital for Diseases of the Skin, Leicester Square, W.C.

Field, F. E., M.B., Ch.B.Edin., Clinical Assistant at St. John's Hospital for Diseases of the Skin, Leicester Square, W.C.

Hare, T. G., M.D., Freib., Pathologist and Bacteriologist to St. John's Hospital for Diseases of the Skin, Leicester Square, W.C., vice R. W. Brimacombe, M.D., resigned.

Births.

Dent.—On June 1st, at 20 Royal Parade, Cheltenham, the wife of Ernest A. Dent, M.B., C.M., of a daughter.

Haward.—On June 5th, at 55 Priory Road, London, the wife of Walter Haward, M.B., B.S., of a daughter.

Lloyd.—On June 4th, at Mackay, Queensland, the wife of George Tyndale Lloyd, M.B., J.P., of a son. (By cable.)

Marriages.

Herron—Brice.—On June 5th, at St. Michael's Parish Church, North Kensington, London, W., Robert T. Crosthwaite Herron, M.D., M.R.C.P.E., of 6 Victoria Street, Armagh, to Evelyn Maud, fifth daughter of the late Frederick Augustus Brice, M.D., Deputy Inspector-General of Hospitals and Fleets, R.N., and granddaughter of the late Lieutenant William Henry Goddard, R.N.

Braddon—Josling.—On June 6th, at Holy Trinity Church, Upper Tooting, William Vaudrey Braddon, M.B.Cantab., of London Road, Thornton Heath, to Beatrice, second daughter of the late George Frederick Josling, Suffolk, and Mrs. Josling, Tooting.

Bywater-Ward—Lawford.—On June 6th, at St. Luke's Church, Thurnby, Leicester, Lieutenant John R. Bywater-Ward, R.N., younger son of the late John Bywater-Ward, M.D., and Mrs. Bywater-Ward, of St. Giles', Oxford, to Winifred Fisher, daughter of Mr. and Mrs. James Lawford, of Bushby, Leicester.

Corley—Watson.—On June 4th, at St. Matthias' Church, Adelaide Road, Dublin, Henry Hagarty Corley, second son of the late Anthony H. Corley, M.D., F.R.C.S.I., of 16 Merrion Square, to Janet Agnes Violet, only daughter of Sir William Watson, D.L., of Fitzwilliam Place, Dublin.

Hunt—Whiteley.—On June 5th, at Ockbrook, Derbyshire, Sydney Hunt, M.R.C.S.Eng., L.R.C.P.Lond., of Spondon, Derbyshire, son of Richard Hunt, of Woking, to Mabel Mary, elder daughter of W. A. Whiteley, of Borrowash.

Deaths.

Bromley.—On May 31st, at Nottingham, Emma, widow of Charles Nelson Bromley, M.R.C.S., formerly of Stafford, in her 89th year.

Lascelles.—On June 5th, at Eatons, Haywards Heath, the wife of J. Eaton Lascelles, Esq., M.R.C.S., L.R.C.P., prematurely, of a son, stillborn.

Moir.—On June 5th, at Calcutta, Major David Macbeth Moir, M.A., M.D., I.M.S., Professor of Anatomy, Medical College, Calcutta, eldest son of the late Dr. Moir, St. Andrews.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXIV. WEDNESDAY, JUNE 19, 1907. No. 25

NOTES AND COMMENTS.

Lord Howard de Walden and Mr. Eastes.

LAST week, in the Chancery Division, an action was brought by Lord Howard de Walden against Mr. Leslie Eastes, M.B., B.Sc., the well-known clinical pathologist, to restrain him from using No. 62, Queen Anne Street, as a laboratory of pathology. It seems that when Mr. Eastes started practice in his special line in 1901, he took a sub-lease of part of these premises from the then tenants, who were under covenant with Lord Howard de Walden's agent not to allow or suffer any trade or business to be carried on in them, though they might sub-let the house for professional chambers or offices. When it came to the agent's ears that Mr. Eastes was using his chambers or offices for the purpose of examining pathological material instead of pathological persons, there was a great to-do, and he was only spared eviction through the good offices of Sir Alfred Fripp, who by personal influence obtained for him a license to "carry on microscopical tests of fluids of the human body in the basement portion of the said premises and to affix one name-plate outside the premises." There were numerous conditions attached as to not annoying or causing a nuisance to the noble lord, his heirs, assigns, and so on, and a grossly arbitrary clause enabling the license to be revoked at three months' notice, apparently entirely at the pleasure of Lord Howard de Walden. Last year the tenant of the premises died, and the wife assigned the whole house to Mr. Eastes, who thereupon equipped it more completely for his work, and adapted some of the ground-floor rooms for laboratory work. He also—heinous offence!—put up another name-plate on the door. On the ground of these alterations and the name-plate, and also because investigations by other than "microscopical" methods, and on other objects than the "fluids of the human body," were carried on, the license was revoked by Lord Howard de Walden.

Microscopical Tests and Macroscopical Prejudice.

Now, considering that Mr. Eastes, by his foresight in choosing his position, together with his care and accuracy in examinations and reports had built up a large connection among medical men, suddenly to turn him neck and crop out of his premises because he technically violated the arbitrary conditions of his lease, strikes us as a piece of high-handedness of the most tyrannical order. There is no suggestion, in the *Times'* report of the trial, that he annoyed anybody except Lord Howard de Walden, and Mr. Justice Swinfen Eady, in deciding that the notice was within the terms of the contract and therefore technically valid, spoke in high terms of the useful and skilful work Mr. Eastes was doing, and in granting the injunction, as he had no option but to do, gave him three months' special grace in which to make fresh arrangements. While congratulating Mr. Eastes on having drawn such high praise from the judge, we offer him our sincere condolences on his treatment by Lord Howard de Walden. The prejudice that exists in noble bosoms against scientific work is usually on a par with the ignorance of its character that exists in noble brains, and we should be interested to learn what "microscopical tests of fluids of the human body" the haughty peer and his advisers contemplated being made, for to no one outside the House of Lords does the sentence convey much meaning. But no amount of ignorance or prejudice will prevent the average West-end noble landlord getting his pound of flesh out of the tenants he "inherits," and we presume that Lord Howard de Walden is satisfied now that he has succeeded in giving Mr. Eastes a blow from which, unless his clients stick closely to him, he may never recover. The name Lord Howard de Walden had none too sweet a savour in the public nostrils during its tenure by the late holder, and the present peer will hardly bring it back into good odour by this magnificent vindication of the rights of British property against the industry, skill, and scientific advance of the British citizen.

The G.M.C. and Dental Partnerships.

WE are thankful to be able to record that in the Appeal Court last week, before the Master of the Rolls, Sir Gorell Barnes, and Lord Justice Buckley, the important case, Hill *v.* Clifford, was settled in diametrically opposite fashion to that in which it was decided in the Court below. It may be remembered that Dr. H. F. Hill was partner in a dental practice, with Messrs. Ruby and Isidore Clifford, and that the two latter were struck off the Register by the General Medical Council, after being charged with employing unregistered assistants and issuing improper advertisements. Dr. Hill then determined his partnership on the ground that he had a clause in his agreement enabling him to do so if either party were found guilty of professional misconduct. Mr. Justice Warrington, who tried the case in the first instance, with penetrating acumen argued that the proceedings before the General Medical Council were not admissible as evidence, and that, therefore, he had no evidence before him on which to find professional misconduct; consequently, he found for the Cliffords, and left Dr. Hill in the anomalous position of not being able to separate himself from his partners, and yet being amenable to the General Medical Council for not doing so. This truly lawyer-like *impasse* was cleared up by the Appeal Court last week, and Dr. Hill is free to do as he wishes with regard to leaving his partners. It is hardly possible for an educated man not a lawyer to understand the puerile, or rather ostrich-like, attitude, of Mr. Justice Warrington in refusing to recognise patent facts when, by his refusal, he brought about a ridiculous miscarriage of justice; but, happily for the credit of our legal system, it has been shown that there is a way of reducing such farces to their proper level.

Livingstone College.

We have received the last annual Report of Livingstone College, with a request that we may say a few words about it. The College, as many readers doubtless know, is one for giving a certain medical training to men who are going out as missionaries to the heathen (abroad). The full course of this training extends over nine months, but students can enter for one or two terms if they wish, though the management naturally prefer them to take the whole course. It seems that though the College has done a good deal in the way of training missionaries, it is still not completely paying its way, and more students are wanted. Though we have no doubt that it is an excellent thing for missionaries to know how to treat a simple wound antiseptically, and what quantity of quinine to take as a prophylactic for malaria, we confess that we see many dangers and temptations in placing a little medical knowledge in the possession of men who are going to districts where they will frequently be the only Europeans. We see too much of the attractions of amateur doctoring in a civilised country not to fear that the novitiate cast on his own resources may be tempted to indulge in experiments, which may bring the white man's medical skill into disrepute with the natives. Surely, if medicine is worth studying, it is worth studying well, and there certainly is no civilising and humanising agency to compare with skilled medical practice. For our own part, we find it difficult to recommend a system of unqualified practice among natives which we would condemn if pursued at home, and we notice from the report that some of the Livingstone alumni seem to practise quite extensively. There are doubtless many difficulties surrounding the subject, but we cannot but remember that Livingstone himself was a qualified and skilful medical practitioner, as well as a missionary and explorer.

A Confusion of "Doctors."

There were certain disclosures at an inquest at Liverpool on June 10th, which seem to call for the investigation of the medical protection societies. The subject of the inquest was the infant child of a labourer, whose wife was attended at her confinement by a midwife. The child was born prematurely, and as it was very puny the midwife suggested that a medical man should be called in. After some discussion, a "Dr. Hamilton Williams Jolly" came and from the midwife's evidence there seemed to be some confusion between him and a "Dr. Fitzgerald." At the inquest, Mr. Jolly said he had a certificate from America and that he was conducting the business which used to be carried on by his brother-in-law, Dr. Fitzgerald. He also confessed that he had given certificates in the name of Fitzgerald, and had been fined for doing so. The curious part of the case was that a certificate signed "J. Fitzgerald, physician and surgeon," was then read by the Coroner, in which it was stated that the child was born prematurely and died from debility. Dr. Fitzgerald was then called, and said that he knew Jolly had been carrying on business in his (Dr. Fitzgerald's) name a year before, and had been fined for doing so but that "it was past and gone." Further, he said that he had been called in to the present case by Mr. Jolly, but did not charge anything. If Dr. Fitzgerald is Jolly's brother-in-law, it must be difficult to avoid him altogether, but if he even appears to have any dealings with an unqualified practitioner, he not only compromises the practice of medicine, but is apt to compromise himself. It is impossible to be too discreet in any dealings with an unregistered practitioner.

LEADING ARTICLES.

THE MONOPOLY OF HOSPITAL APPOINTMENTS.

In our correspondence columns appears a letter from the President of the Association of Medical Diplomates of Scotland, calling attention to the exclusion of Scotch and Irish diplomates from the majority of London hospital appointments. The grievance is one of long standing, and applies not only to the Metropolis, but to many of the large provincial medical charities in addition. The fact that both in Scotland and in Ireland various similar posts are restricted to those holding such qualifications is no adequate answer to the complaint. First of all, we believe that such restriction is only limited in extent, and that its existence is not likely to injure materially the few Englishmen who may wish to settle in Scotland or in Ireland. Moreover, in some at least of the leading hospitals and infirmaries of Scotland the possession of one of the higher English qualifications is made a *sine qua non*. The case of the holders of Scotch and Irish qualifications residing in England, however, assumes an entirely different aspect. There are many thousands of men practising under such conditions in English urban and rural districts, and their exclusion from the majority of hospital appointments constitutes a standing injustice to themselves and an insult to the Scotch and Irish Corporations from whom they have obtained their diplomas. For many years past the Irish Graduates' Society have protested against this unfair exclusion, and in not a few instances have succeeded in securing its removal from the rules of provincial hospitals. The Scotch diplomates have now followed suit with an energy that augurs well for the future. Under present circumstances the rules of practically all the great hospitals and infirmaries in London and the provinces make the holding of one of the higher English qualifications an essential condition for posts on the honorary medical and surgical staffs. The result is to place a valuable monopoly in the hands of the English colleges and the English diplomates at the expense of the holders of Scotch and Irish qualifications. In most cases the rules have probably come into existence without the attention of governors having been called to the existence of any condition of the kind. So obviously unfair is the proceeding that in several provincial towns it has only been necessary to inform the local supporters of a charity of the fact to secure its immediate repeal. The whole matter, indeed, appears to have drifted into the position of an old-fashioned anomaly which, however unjust, has become sanctioned by usage. It seemed unlikely that fresh institutions would be called into being and endowed with so obnoxious a condition. Yet that is precisely what appears to have happened in the case of the amalgamated London Orthopædic Hospital. Three hospitals were united into one institution. Of these, two admitted Scotch and Irish diplomates; the other did not. Incredible as it may seem, the charter of the amalgamated hospital excludes any but holders of the higher English qualifications. Worst of all, the Hospital Sunday and the King Edward's Funds, who pressed forward the amalgamation scheme by every means in their power, seem to have sanctioned this grossly unfair exclusion. They cannot plead ignorance, for attention has been repeatedly drawn to the point in the columns of The Medical Press and Circular. On January 18th, 1905, in a leading article, we appealed to both the Funds mentioned "to examine the whole of the circumstances attending the sale of the site and the amalgamation of the Royal Orthopædic Hospital." The wisdom of the sale of that valuable freehold, the sole birthright of that particular institution, under the chairmanship of Mr. H. H. Marks, was, in our opinion, open to grave question. We have no evidence that either of the Funds that pressed for amalgamation took either the financial aspect or the possible exclusion of Scotch and Irish diplomates into consideration. The irresponsibility of the Funds under present circumstances renders remonstrance and inquiry of no avail. They are autocratic and unrepresentative, and so long as they rest on such a constitution, so long will they fail to secure the full confidence of the public. We feel, however, that the time has now arrived when the Hospital Funds and the public that support the hospitals should be fully informed of the fact that an honourable body of men are excluded from the great majority of English hospital appointments simply because their medical qualifications were obtained in Scotland or in Ireland. The present state of affairs forms a strong argument in favour of the one-portal system. A single qualification is good enough for law and lawyers, but medicine is reached through many qualifying approaches. When medical men follow the example of the legal profession and sink all individual rivalry in the wiser policy of collective protection, then unjust competition and privilege of all kinds, whether within or without the camp, will have to hide their diminished heads.

PUBLIC CHARITY AND UNQUALIFIED MEDICAL PRACTICE.

Medical men generally have themselves to thank for much of the encroachments upon their legitimate field of practice by unqualified pretenders. They are not sufficiently alive to the necessity of educating the public of the precise dangers they are incurring by the use of quack medicines and by resorting to quack practitioners. Nor have they yet come to recognise that the proper way to render their own position one of security is to abandon internal squabbles and insist upon the absolute need of the consolidation of the laws affecting the medical profession. One of the first requisites is to amend the constitution of the General Medical Council, so as to make it representative of the medical profession, and to endow that body with powers of prosecuting unqualified practitioners akin to those possessed by the Incorporated Law Society. The next step should be the passing of a new medical Act rendering the performance of medical acts generally by unqualified persons a punishable offence. Possibly, or probably, the best way of opening up a vigorous campaign would be the appointment of a Royal Commission of Inquiry, a step that has repeatedly been advocated in our editorial and correspondence columns. Meanwhile, the necessity of unceasing vigilance is being emphasised from all sides. Only last week, the secretary of a body described as the Incorporated Society of Extractors and Adaptors of Teeth, appeared before the Select Committee of the House of Lords sitting to examine the bills prohibiting medical practice and restricting dental practice by companies. He advanced the specious plea that in 1,750 towns and villages in Great Brtiain there is no registered dentist, and the members of his society accordingly meet a great public want in those places. How would the Incorporated Law Society deal with an appeal to permit legal work to be conducted by unqualified persons in towns and villages unblessed by a resident solicitor? Medicine, no less than law, should be vigorously protected by the State against the encroachments of ignorant and unqualified pretenders. So insidious is the evil that some classes of quack are taken under the protection of fashionable society. A whisper has even been raised that the Lord Mayor of London has in contemplation the services of expert but unqualified help as regards the cripples whose cause he has so strenuously and successfully advocated. It is impossible to believe for a single moment that a man of the tact and experience of Sir William Treloar would be betrayed into such an indiscretion. We are constantly reminded, however, that philanthropy and wisdom do not usually go hand in hand. Especially is it wise for the medical men connected with the administration of the medical charities, to keep a watchful eye upon the vagaries of executive and administrative bodies. In that way alone may it be hoped to protect the public as well as medical practitioners against the great evil of irregular medical practice.

CURRENT TOPICS

The Discussion upon Cancer in the Lay Press.

Since the latter end of last year, when a Dr. Saleeby contributed a series of flamboyant articles to the *Pall Mall Gazette*, entitled the "Conquest of Cancer," which forsooth must have caused a sad smile of compassion for the writer from his medical readers, the lay press has periodically published various contributions upon cancer. But the past two weeks have seen a violent recrudescence of this effort to inform the public regarding this disease. The *Daily Mail* has distinguished itself by publishing a series of articles entitled "The War Against Cancer." When the "Conquest of Cancer" article appeared we were led to infer that there was nothing more to conquer, and that the war with the disease had come to an end. But it now seems from the *Daily Mail* that the war is still going on; indeed, if our judgment be sound, that hostilities are in a very active state. We confess to a great deal of disappointment at having had to arrive at this conclusion; a disappointment which, no doubt, has also visibly impressed itself upon the public generally. There is so much difference between war and peace that even to the most insignificant person no difficulty is caused in distinguishing between the two. Nevertheless, having had our best hopes ruthlessly shattered by this renewal of hostilities, we can only conclude that something must have gone wrong with the article announcing the "Conquest of Cancer," despite the all-pervading self-assertiveness in which the writer conveyed his convictions. So far, however, as the *Daily Mail* articles are concerned, we could not presume to criticise them; they are beyond criticism. The writer has evidently powers of prescience and observation to which we cannot attain. With becoming modesty we still feel disposed to describe ourselves as ordinary mortals to whom our sublunary abode is at present a matter of necessity. As it is we are quite incapable of following the writer into that phlogistic realm of fancy which confers the power upon a surgeon of saying when a cancerous growth is dead as the result of the administration of trypsin. We gather, however, from the writer that when the surgeon has diagnosed the dead growth, whose melancholy decease has thus been brought about, he must at once administer amylopsin, which acts as a sort of family besom, and sweeps all the dead cancer away. After that the patient is cured. All this is most impressive. We are now able to grasp how easy a matter the subject of cancer really is.

The Medical Manifesto.

The manifesto recently issued in favour of alcohol is being circulated under conditions that must be somewhat distasteful if known to the signatories. It is being circulated broadcast presumably in the interests of the wine and spirit trade. Moreover, we are informed by one correspondent that he has seen it posted in public-house windows. In any case the issue of such a manifesto illustrates the unwisdom of any medical declarations that may be made use of by trade capitalists or by interested politicians. The names of the signatories are about the last that medical men would expect to see appended to unwise public documents. *Nemo omnibus horis sapit.*

The Coventry Dispute.

The Coventry fight has entered a new phase. We regret to say that the Dispensary Committee have succeeded in getting candidates for the posts on the medical staff which were recently vacated by the local medical men, and three qualified men—Messrs. I. Inman-Langley, A. P. Blanchard Ellis, and A. St. Laurence-Burke—have been elected medical officers to the institution. There seems to be no misunderstanding on the part of these gentlemen as to the state of affairs prevailing at Coventry, and they presumably are aware that they are stepping into the shoes of medical men who resigned their appointments on questions of principle. What the consequences will be with regard to the support accorded by the patients remains to be seen, but if the new members find themselves in a position even more uncomfortable than their predecessors they will hardly expect much sympathy from their colleagues. At the annual meeting of the Dispensary there was a great deal of blarney and bluster on the part of the chairman and members of the committee, appeals not to "desert the old ship," and so on, but reading between the lines it looks as though there was not so much confidence in the success of their cause after all, especially as in the chairman's speech he intimated that there was a possibility of the Coventry Hospital not recognising patients sent to it by the dispensary authorities. The battle, he said, would begin on June 24th, and its issue we shall watch with keen interest, and the fervent hope that right and justice may triumph.

Dirty Milk and Infantile Mortality.

The problem of infantile mortality is one of the most serious problems with which the health authorities of all large cities have at present to deal. In Dublin, for instance, it was stated by the medical officer of health the other day that the death rate among children is the same as the average in seventy-six great towns of England. This is a very bad record when it is remembered, as Sir Charles Cameron added, that babies in Dublin are almost entirely breast fed. Probably in no city in the kingdom are there so few mothers employed in industrial work. In the causation of disease among older children there is little doubt that dirty milk plays an important part. Sir Charles Cameron made an urgent plea that the Department of Agriculture should take on the duty of supervising at its source the milk supply of Dublin. This, however, would seem to be the duty of the Dublin Corporation, and only a few weeks ago we had to chronicle the refusal of the Corporation to take any steps to obtain greater powers over the milk supply of the city. Though the Corporation has no power to inspect dairy-yards outside the city, it has ample power to deal with milk exposed for sale which is adulterated or unfit for food, and we fail to see any justification for the attempt to shuffle responsibility on to the Department of Agriculture.

The British Medical Association and its Charter.

After the discussion at the special Representative Meeting of the British Medical Association a week or two ago, it is not likely that the movement in demand of a charter will proceed much further for the present. The Dublin Division, while approving of a charter in the abstract, moved that the consideration of it be postponed to allow of fuller discussion of its terms. The Glasgow division wished to go further, and expunge any expression of approval. It is obvious that the demand has no chance of success unless it be practically unanimous on behalf of the Association, and the support given to the Dublin proposal shows that there is little prospect of any unanimity at present. On a vote, the proposal was lost by 81 votes to 34, showing that a minority of nearly one-third of the Association is opposed to the present demand. In this minority are to be numbered, in addition to the divisions mentioned, such important constituencies as Lancashire and Cheshire, Liverpool, and the Northern Counties of Scotland. As Dr. Bradshaw pointed out, the demand for a charter, if it is pressed, will be in the teeth of a determined opposition, so that it is hardly likely that those in its favour will engage themselves in a hopeless fight, and embarrass the Association with heavy and fruitless expenses.

PERSONAL.

It has been arranged that the ceremony of presenting the Freedom of the City of London to Lord Lister shall take place at the Guildhall on the 28th inst. at 11.30 a.m.

Sir William Church has been elected first President of the Royal Society of Medicine.

Dr. Dearden, the medical officer of health for Douglas, has resigned the position through ill-health, and the Douglas Town Council have passed a motion of regret, and decided to advertise for a successor.

Dr. E. Hooper May, one of the honorary surgeons at the Prince of Wales' General Hospital, was presented with a gold sovereign purse and match-case in connection with the celebration of his golden wedding on Thursday last.

Dr. Charles W. Chapman, took the chair at the annual dinner of the Durham University Medical Graduates Association.

Dr. Joseph Smith has received the King's permission to wear the Order of the Lion and the Sun (Second Class) conferred on him by the Shah of Persia for medical distinction.

Sir Thomas Barlow, Bart., took the chair at the meeting at Queen's Hall, organised by the *Tribune*, to urge on the Government the duty of excluding children from public houses by legislation.

Dr. C. W. Newton, who has twice been Mayor of Newcastle, was presented on June 6th with an illuminated address by the trades and friendly societies of the City to commemorate his forty years' work on the Corporation.

In honour of the memory of Mr. James Smith Turner, a "Smith Turner Scholarship in Dental Mechanics" has been founded for deserving students. The first examination will be held at the Royal Dental Hospital, London, on April 8th, 1908.

Dr. A. F. R. Wollaston, who was sent out by the British Museum last year to explore the Ruwenzori region of Africa, has lately returned safely home.

Sir Richard Douglas Powell, and Professor Watson Cheyne are to be the recipients of the Honorary D.Sc. at Oxford at the next Encoenia.

Dr. W. A. Densham, of the East African and Uganda Medical Service, has, we regret to learn, been killed by a buffalo, while out shooting.

In conferring the honorary degree of Doctor of Science of Cambridge upon Sir Thomas Fraser, the Public Orator referred to his famous dissertation, published nearly forty years ago, upon the Ordeal Bean of Old Calabar, and remarked that it won him early distinction as Laureate of the Institute of France.

Mr. T. H. S. Pullin, of Sidmouth, was recently presented with a silver salver and an address by past and present members of the Honiton Board of Guardians, in recognition of fifty-seven years of public work.

Professor J. J. Charles, M.D., has been presented by the medical students of Queen's College, Cork, with an address and a handsomely-illuminated album on the occasion of his resignation of the Chair of Anatomy and Physiology.

Cerebro-spinal-Meningitis has already made a victim in the medical profession, namely, Signor Lampagnani, of Rome.

Mrs. Mary Scharlieb, M.D., M.S., will open a discussion on "Alcohol, and the Children of the Nation" at the next meeting of the Society for the Study of Inebriety, at the Rooms of the Medical Society of London, on Tuesday, July 9th, at 4 p.m.

The late Mr. John W. Taylor has left £100 each to the Sheffield Royal Hospital, the Jessop Hospital for Women, Sheffield, and the Sheffield General Infirmary.

At a meeting of the Board of Cardiff Infirmary on June 12th a letter from Dr. Tatham Thompson was read, in which he stated that he had completed his service of twenty years as an ophthalmic surgeon, and, consequently, his office as an acting member of the staff terminated. On the motion of the Chairman, seconded by Dr. Wallace, Dr. Tatham Thompson was appointed consulting ophthalmic surgeon, and the meeting recorded its great appreciation of the valuable services he had rendered to the institution.

A Clinical Lecture

ON

DISORDERS OF MICTURITION IN WOMEN (a).

By PETER HORROCKS, M.D.Lond., F.R.C.P.,

Senior Obstetric Physician, Guy's Hospital, Lecturer on Obstetrics and Diseases of Women, Guy's Hospital Medical School, &c.

Gentlemen,—The frequency with which women complain in regard to trouble of one kind or another in micturition, makes it certain that when you get into practice you will often be consulted for the relief of such suffering. In order to be able to give relief, and in order to understand the varied causes of micturition troubles, you should know the anatomy of the parts, how they differ from those in the male, and how they are apt to be disturbed by causes which never act in the male. The bladder of a woman is said to be rather more capacious than that of a man, and this is said to be due to her habit for countless generations of holding her water a longer time than men do, for reasons of modesty and lack of conveniences. Again the urethra in women is a short and comparatively wide tube, a fact which explains some of the differences between women and men in regard to micturition troubles.

Also, you should understand the physiology of the act of micturition. Is it voluntary or reflex ? It is certainly a reflex act, but it is largely under the influence of the will.

The stimulus arises when the bladder contains a certain amount of urine, and grows in intensity up to a limited extent, with the increase of the amount. The afferent impulses are conveyed to a centre in the spinal cord but the Will can, up to a certain point inhibit the effect of these afferent impulses passing down to the micturition apparatus. When it is convenient the will power can set the apparatus in motion,

The detrusor fibres of the bladder are set in motion by the efferent impulses, and at the same time the sphincter vesicæ is relaxed and so the urine is voided. Normally the abdominal walls are not required to assist, but they can be made to do so either to increase the speed or to overcome any obstacle.

The bladder can empty itself by a purely reflex act, as for example in children when they wet the bed during sleep, or in persons whose spinal cord is so injured above the micturition reflex centre as to cut off the influence of the will. A gamekeeper generally squeezes out the contents of the bladder of a recently killed rabbit, before putting it in his pocket because he knows what would happen if he did not.

When the bladder is empty its walls are more or less in contact. In other words it contains a potential and not a real cavity. In this condition it measures from the meatus externus five inches, of which an inch and a half belong to the urethra. As the urine gradually accumulates the walls are separated, and it can contain a pint without its length being increased. It may be considered to be quite full when it contains a pint, and over-distended when it contains more than a pint. Its walls are thinner when it is full (still thinner when over-distended) and thicker when it is empty. When it is filling the walls are gradually stretched and so the muscular fibres are elongated. which places them in a position not only to actively contract, but also to shorten When the act of micturition is finished and the bladder is empty, the muscular walls of the bladder are in a state of retraction, the muscular fibres of the bladder, like those of the rest of the body cannot elongate themselves, and they have no muscular opponent (like most muscles have) to do this. But the *rôle* of opponent is performed by the accumulating urine.

RETENTION OF URINE.

The most frequent trouble and the most important in women in regard to micturition is retention. Owing to the short wide urethra, retention would be far less common in women than in men were it not for one important cause, namely *parturition*. When the child's head descends into the pelvis the neck of the bladder and the urethra are compressed more or less, and, as all doctors and midwives know, it not infrequently happens that a woman cannot pass her water properly for a day or two after labour. It is this most important cause which renders retention of urine as common in women as in men, and you should always give it as the first cause if ever you are asked the question at an examination. When you get into practice you will learn it by experience and sometimes by very unpleasant experience, If a woman passes no urine after labour attention is at once drawn to the fact and she is relieved by some method of getting her to pass water, or by catheterism. But you may come to grief with women who pass *some* urine, but who do not empty the bladder which gradually gets more and more distended. In such a case the nurse may tell you,. and honestly believe it, that the lady is passing her urine all right. If you accept the nurse's statement you ought to accept the responsibility. I remember a medical man fetching me to his wife, who, he feared, had puerperal fever. It was the fourth day after labour, she had had a rigor and her abdomen was distended and she was in great pain. On arrival at the house the patient certainly looked ill, and in distress, but on examining the abdomen it was obviously an enormously distended bladder which caused the abdomen to be enlarged, for it was dull in front, resonant at the sides, fluctuating and of the peculiar pyriform shape which the bladder assumes. A catheter was passed, over six pints of urine withdrawn, and the patient's distress was immediately relieved. The doctor was very angry with the nurse because he said she had assured him that his wife had passed her water all right. This is only one of many cases which I could relate to you, where a lady has apparently passed her water all right, and in the opinion of the nurse, in sufficient quantities, and yet where the bladder has gradually become distended. Let me advise you therefore, not to accept the nurse's word without confirming it by feeling the abdomen in the region of the bladder particularly if there be any distress, or by passing a catheter if need be, in case you are in doubt.

(a) Two Clinical Lectures delivered at Guy's Hospital, October, 1906, and January, 1907.

After abdominal section, if a catheter is not used, and the patient is supposed to pass water herself, you may get this gradual filling of the bladder, causing distress and simulating distention from peritonitis.

The next great cause of retention of urine is a *retroverted gravid uterus.* The uterus may be retroverted before pregnancy, or it may become so after it has become pregnant. In either case as it gradually enlarges it fills the pelvic cavity and the cervix uteri, presses against the urethra, and the neck of the bladder. As a rule, it is during the fourth month of pregnancy that the pressure becomes so great as to prevent the emptying of the bladder. Again, the woman may not complain of retention of urine, because she may be passing *some*, though it does not strike her that she is passing too little. For the same reason the nurse may, in answer to a direct question, reply that the urine is voided all right. Of course, if the patient cannot pass water at all, your attention is drawn to it but in other cases you may be called in on account of pain and swelling of the abdomen.

A medical man once asked me to see a case with him, and on the way he told me that the patient said she was only four months pregnant, but that he considered her to be six months at least.

On examination a four-months' retroverted gravid uterus was found in the pelvis, and an enormously distended bladder, rising above the umbilicus in the abdomen. We drew off nearly eight pints of urine and then restored the uterus to a normal position by means of digital pressure and she went on to term afterwards.

As we came away he said: "That confounded nurse told me that she was passing her water all right or I should never have made such a mistake."

So let me impress it as forcibly as I can upon your minds that a woman may be suffering from retention of urine, even when you are told that she is passing urine all right. Keep it in your mind, and if you find a suspicion of distention of the bladder, or if you are unable otherwise to eliminate the possibility, by all means pass a catheter to make sure.

In the case of retention from a gravid retroverted uterus you get a vicious circle. For the pressure against the urethra causes retention, and the distended bladder prevents restoration of the uterus.

A third cause of retention of urine in women is *hysteria*, and is met with chiefly in unmarried young women. Do not mistake hysteria for malingering and *vice versa*, and remember that you may have both at the same time in the same patient.

Retention is apt to follow operations on the vulva, vagina, uterus, peritoneum, bladder, rectum, abdominal walls, hernia, and even after operations on parts more removed from the bladder than those already enumerated. After an abdominal section a patient may be unable to pass any urine, or she may be able only to partially empty the bladder. Often enough urine is withdrawn by means of a catheter every six or eight hours for a day or two chiefly in order to keep her quiet and to subject her to no effort at all of her own. Where this is not done, it sometimes happens that the bladder gradually distends, and if some urine is voided, and so attention is not directed to the bladder, it may be mistaken for peritonitis, I could tell you of many instances illustrating this, but I will content myself with drawing your attention to it, in order that you may be on the *qui vive* for such a condition.

Pressure from tumours may cause retention. You will find this is by no means a frequent cause. For example, fibroid tumours of the uterus are extremely common, and yet retention due to such growths is very rare. Probably the reason of this is that they are slow growing things, and so the parts are able to accommodate themselves *pari passu.* I have certainly seen retention caused by a fibroid, but it was due to an accident or to straining. A young lady out hunting was thrown from her horse whilst leaping a ditch. She came down to the ground very forcibly, but fortunately without being much injured. Nevertheless when she got home she was unable to pass urine. Her doctor passed a catheter and on rectal examination (as she was single) he felt a large tumour in the pelvis. On seeing her with the doctor, I recommended an operation, and we removed a fibroid tumour as large almost as a fœtal head. It was of the sub-peritoneal variety, attached to the uterus by a thick pedicle. Its presence had not been even suspected before the accident, and what had most likely been the case was that it lay chiefly above the pelvic brim so causing no trouble, but that the sudden concussion when she was thrown, forced it down into the pelvic cavity, and so produced sufficient pressure to cause retention. It was removed without removing the uterus, and later on she married and had children.

Again, cystic tumours are common, but they seldom cause retention. Curiously enough small tumours are more prone to do so than large ones. That this is so may be due to the fact that small ones are often held down in the pelvis by some anatomical or pathological bands. Thus broad ligament cysts are held down by the layers of which that ligament is composed. But cystic tumours even when they grow rapidly accommodate themselves to the surrounding parts owing to their mobile fluid contents. Hence the rarity of retention of urine caused by such tumours.

Cancer in the urethra or vagina or cervix uteri may block the urethra and so cause retention. But it is only rarely that cancer does this. Far more frequently it causes incontinence by producing a fistula.

Inflammation in the neighbourhood of the bladder, pelvic peritonitis, either local or as part of a general peritonitis, perimetritis, parametritis, especially when in front or between the uterus and the bladder, all these may cause retention.

Certain *nerve diseases*, of the spinal cord, or brain, and certain mental affections, cause, or are at all events accompanied by retention of urine. Rarely it is seen in locomotor ataxia, and in some forms of paraplegia.

Similarly it is occasionally met with in the *continued specific fevers.*

Calculus as a cause of retention is almost unknown in women. The urethra is so short and wide that small calculi are easily passed, and only very rarely stick fast in, and block up the passage. Large calculi, are rare in women and when they do occur cannot get into the urethra.

Stricture of the urethra is almost unknown in women. I have never seen a case following upon gonorrhœa, as is so commonly the case in men. Theoretically it might occur, and you may have stricture following upon ulceration, injuries, operations caustics, or they may be congenital. Still you may go through a long life of busy practice and never meet with a case.

Lupus maximus may block the urethral orifice, and so cause retention Lupus minimus produces painful micturition so causing a woman to hold her water a long time.

Syphilitic adhesions might block the meatus, and also *elephantiasis*.

It is remarkable that in cystocele patients rarely find any difficulty in emptying the bladder. The detrusor fibres can expel the urine, although the bladder is upside down and out of the reach of the pressure exerted by the abdominal muscles for the most part at any rate.

TREATMENT.

After parturition not only see that the patient is passing enough urine by asking the nurse to tell you as near as she can the amount, but also palpate and percuss over the bladder whenever you suspect retention, and if you find it, or if the patient is not well, and you don't find it, pass a catheter. In some cases you may have to pass it every six or eight hours. As a rule the bladder and urethra recover their lost tone and micturition. becomes normal in a few days. If they do not you must continue to use the catheter, or still better drain the bladder by means of a self-containing catheter, the sigmoid shape being the best.

In retroverted gravid uterus draw off the urine with a catheter, restore the womb to its normal position and fit her with a suitable pessary to prevent remalposition, and let her wear it until the end of the fourth month of gestation after which the uterus is too large to be retroverted. As a rule it is not necessary to repeat catheterism if the uterus can be restored. If it cannot then you should keep the bladder emptied by a catheter until the trouble is overcome. It would take me beyond the limits of this lecture to deal with irreducible retroverted gravid uterus.

In hysterical retention you should draw off the urine with a catheter and satisfy yourself that there is no organic lesion, and then if the retention recurs let the catheter be used only as a last resource, and even then by the nurse or female relative or friend. The condition is soon cured in this way.

After operations the bladder soon recovers itself if kept from over-distention by means of catheterism. When due to the pressure of tumours of course these must be removed if possible by operation. Sometimes it is possible to relieve the pressure by pushing them into a different position. Inflammatory products must be absorbed or let out, relieving the bladder by catheterism in the meantime. In cases of nerve disorder and of insanity, where retention is present it is important to prevent over-distention by passing a catheter regularly, or by fixing a self-retaining catheter. A calculus must be removed, and anything blocking the urethra at the meatus urinarius must also be removed. A cystocele can usually be restored wholly or partially and kept in position by means of a suitable pessary or by operation.

Retention of urine in the ureters and kidneys may be caused by the pressure of tumours in the pelvis and abdomen and by collections of blood (hæmatocele) pus, or other fluids. A calculus more often met with in the ureter than in t urethra, but is as a rule on one side only.

NOTE.—*A Clinical Lecture by a well-known tea appears in each number of this journal. The lect for next week will be by Peter Horrocks, M.D.Lon F.R.C.P., Senior Obstetric Physician, Guy's Hospi Lecturer on Obstetrics and Diseases of Women in Gu Hospital Medical School, etc. Subject : "Disorders Micturition in Women." (Being the second of t lectures delivered at Guy's Hospital.)*

ORIGINAL PAPERS.

CEREBRO-SPINAL FEVER (*a*).

By F. M. SANDWITH, M.D., F.R.C.P.Lond.

Consulting Physician to Kasr el Ainy Hospital, Cairo, and Lect at the London School of Tropical Medicine.

SOME statistics from the British Isles durin the first three months of 1907 were given to sho the present prevalence of the disease. As man as 312 deaths occurred in Glasgow from th cause during the quarter, 179 of them havin been recorded in March. This represents higher death rate than from any other acut infectious disease in Scotland.

The history and geographical distribution the disease during the last hundred years we briefly traced. Mention was made of the exis ence of the disease in Nigeria, Egypt, and th Sudan, where the Mahdi is believed to have die of it. But the United States have really bee its headquarters, both as regards extent of pre valence and severity of the disease, for the are for several years has extended from Canada t Mexico and from the Atlantic Ocean to Minnesot and Iowa. It was noticed that new district are constantly being attacked, but that there wa no reason for anxiety with regard to the presen outbreaks in the United Kingdom. The curious irregular type of epidemics, both as to space an time, distinguish this disease ; a local epidemi may smoulder on for months, and may recur a irregular intervals in the same district, showin that the infection is endemic for the time bein in that particular spot, from which it is argued that the poison of the disease can exist for a short time outside the human body.

Though prisoners and soldiers in barracks are specially liable in endemic centres, in ordinar civil life it is children and young adults who ar the most susceptible. Infants of five months have been known to recover, though many babies under one year have succumbed in New York Speaking generally, the older the child the bette are its chances of recovery.

The arguments for and against personal contagion were considered, and the disease was compared to certain outbreaks of pneumonia whic at times in a family or a school may present a high degree of malignant infection. The lecture gave his personal experiences at Boston an New York in the spring of 1905, when he ha the opportunity of seeing dozens of cases by the courtesy of various hospital physicians. In the Boston City Hospital the house physicians an nurses were instructed to wear a gauze muzzl

---

(*a*) Abstract of a Lecture delivered at the Medical Graduates' Coll and Polyclinic.

covering the nose and mouth because the avenue of infection was thought to be through the nasal passages, and the same general instructions were issued that obtain in that hospital in the general management of infectious cases. On the other hand, in New York he found that no great precautions were taken beyond isolating the patients in special wards. Attention was drawn to the fact that the diplococcus is often found in the nose and throat of attendants on patients suffering from cerebro-spinal fever, and in such cases the nose and throat should be carefully disinfected.

Flexner's experiments on monkeys in New York were mentioned. During 1905, in New York city alone, no less than 2,755 cases of this fever were reported, besides, probably, many mild cases which were not notified. Of the number reported 1,511 died, giving a mortality of about 55 per cent. The duration of the cases varied extremely, from nine hours to several months. The incubation period is short, from one to five days. The *diplococcus intracellularis meningitidis* is found in the mucus of the nose in at least half the patients during their first week; it is of feeble vitality, being rapidly killed by drying and on exposure to sunlight, which makes the probability of infection by dust very unlikely.

The cases of posterior basic meningitis, well-known in this country, are due to the same organism, and are therefore only sporadic forms of the disease. Among the differences between cerebro-spinal fever and tubercular meningitis is the fact that in the former the spinal cord is much more involved than in the latter, where the membranes of the brain are chiefly attacked; this is shown by stiffness of the neck, rigidity of muscles, sensitiveness of the skin, great retraction of the head and sometimes opisthotonos. In various cerebro-spinal epidemics the number of recoveries varies from 20 to 50 per cent., whereas in other forms of meningitis recovery is almost unknown. Other points in favour of this fever are the abrupt onset, Kernig's sign (though this is of very little value in children under two years of age), hyperæsthesia, mental irritability, the peculiar skin eruption and herpes on the lips.

The absolute diagnosis is made by the detection of the diplococcus in the cerebro-spinal fluid after lumbar puncture, but it must not be forgotten that the diplococcus may not be found after the first ten days of the illness, and that it is necessary always to use the fluid as fresh as possible.

Cases were reported where the disease had been mistaken for sunstroke, typhoid fever, pneumonia, influenza, typhus, and even nervous symptoms produced by the presence of ascarides.

Several patients in the United States during the last epidemic there were empirically treated with large doses (up to 30,000 or 40,000 units) of diphtheria antitoxin, usually administered intra-muscularly, but sometimes intra-spinally. This treatment was of no avail, and no drug has yet been found as a specific. Repeated lumbar punctures undoubtedly often help to allay the fever, headache, delirium and general irritability of the patient, and the operation has not been followed by ill results, though occasionally there is a little hæmorrhage. Flexner's serum from artificially-infected monkeys holds out hopes of future prophylactic and even curative value.

THE USE OF MASSAGE AND MOVEMENT IN THE TREATMENT OF FRACTURES (*a*).

By C. W. CATHCART, M.B., F.R.C.S.,
Surgeon Royal Infirmary, Edinburgh.

In recent years there have been improved methods of diagnosis of fractures—Röntgen rays, antiseptic incision, as well as improved methods of treatment—Championiere's use of massage and movement, and in a few cases, operation under antiseptic precautions. Our views as to the treatment of fractures have changed greatly, due, to a large extent, to the pioneer work of Lucas Championiere. The old principle in dealing with a broken bone was to secure absolute immobility by fixing the joints above and below with some form of retentive apparatus. It is now known that absolute immobility, instead of being necessary for bony union, is a hindrance to it, and may lead to secondary functional disability, sometimes permanent. On the other hand, massage and movement for a few minutes daily, combined with fixation, hastens bony union, maintains the functional power of the muscles, and minimises adhesions. Many forms of retentive apparatus which were formerly valued can now be dispensed with; those still employed are simpler than before, leave the joints more free, and are taken off sooner. The objects to be attained by massage are the removal of deformity, of swelling, of spasm, and of pain, and the promotion of absorption of effusion into muscles, and about tendons and ligaments. At first passive and then active movement should be practised. There is one rule in both massage and movement, and that is that pain should never be caused. Passive movement ought to precede active movement; the object of the former is to prevent adhesions, while the place of the latter is that of promoting the return of functional integrity. Splints are still needed in the treatment of fractures to prevent deformity in fractures of unsupported shafts of long bones, when the neighbouring joints may be supported but not immobilized, or in some fractures near joints where the long fragment has to be brought into line with the short one. They may also be needed for the purpose of supporting and steadying a recently broken bone because of muscular spasm and pain on movement. Extension is also still necessary to diminish overriding and relieve muscular spasm in certain fractures of the lower limb, but it can generally be dispensed with in from two to four weeks. By the use of massage and movement retentive apparatus is greatly simplified. Taking the case of fracture of the clavicle, all pads in the axilla, &c., can be dispensed with; and if the arm is supported by a bandage, nothing more is needed. Even strapping is, to a certain extent, objectionable. The same applies to fracture of the surgical neck of the humerus; no splints are needed. It is enough to support the arm, and to give early massage and movement. In fracture of the olecranon it is no longer essential to keep the arm extended in an anterior splint; a piece of plaster is applied to steady the fragments, and the arm is kept quiet. The same applies to fractures of the lower end of the radius, of the neck of the femur, of the patella, and of the lower end of the fibula. No particularly skilled massage is needed; a nurse becomes thoroughly competent after a few lessons.

(*a*) Abstract of Paper read at the Edinburgh Medico-Chirurgical Society, June 5th, 1907.

THE CAUSE OF THE HEART BEAT (*a*).

By G. A. GIBSON, M.D., F.R.C.P.Ed., F.R.S.Ed.,

Physician to the Edinburgh Royal Infirmary; Examiner in Clinical Medicine, University of Edinburgh, &c.

The literature which has already grown up in connection with the subject of the causation of the heart beat is enormous. It is quite impossible in the compass of a single lecture to do more than refer to the really important contributions yielding something more than mere destructive criticism. For an excellent summary of the whole question of the cause of the heart beat let me refer to the learned article of Langendorff in the *Ergebnisse der Physiologie*, and let me further add that while this oration was in course of preparation two interesting addresses have appeared on the subject by Wesley Mills and Alexander Morison.

Harvey made no attempt, even in that chapter which forms the most beautiful part of his immortal work, to explain the causes of the pulsation of the heart, and we have to pass on till a period a hundred and fifty years later before we encounter any attempt to define the problem. Cardiac movements were originally attributed by Albrecht von Haller to an inherent power of contraction belonging to the heart itself. It has been claimed that he regarded the automatic movements of the heart as due to an inherent faculty of the heart muscle. This, however, is not specifically stated, and, as the intimate nervous connections were then unknown, it is probable that the intrinsic nature of the movements did not particularly trouble the mind of that great observer. Senac also regarded the pulsation of the heart as due to special activities, but he laid greater stress upon external sources of interference. With these vague views pathologists, as well as physicians, were content until the middle of last century. The discovery of the ganglia at the junction of the sinus and of the auricle by Remak, of those between the auricle and the ventricle by Bidder, and of those between the two ventricles by Ludwig, necessarily opened up the possibility of some definite explanation, and the formal presentation of the views which resulted was given by Volkmann, who enunciated the theory that the pulsation of the heart was due to the automatic action of the intrinsic ganglia of the heart.

These views, however, were almost from the first modified in certain respects from time to time, by the investigations of several observers. It is only necessary to mention the experiments of Eckhard as well as of Foster and Dew Smith upon the apical region of the heart, and the further researches of Bowditch and of Merunowicz on the influence of different nutrient fluids upon the same part. The general result, however, was embodied in the theory, stated by Rosenthal, that impulses flowed from the ganglia in the sinus and produced the rhythmic action of the heart.

In the minds of those, nevertheless, most competent to form a judgment in respect of such facts, a considerable degree of doubt existed in regard to such an explanation. "In the sporadic ganglia," Foster says, "the evidence of automatic action seems more clear, and yet is by no means absolutely decisive. The beat of the heart is a typical automatic action; and, since the heart will continue to beat for some time when isolated from the rest of the body (that of a cold-blooded animal continuing to beat for hours, or even days), its automatism must lie in its own structures. When, however, we come to discuss the beat of the heart in detail, we shall find that it is still an open question whether the automatism is confined to the ganglia (either of the sinus venosus, auricles or auriculo-ventricular boundary), or shared in by the muscular tissue; whether, in fact, the automatism is a muscular automatism like that of a ciliated cell, or the automatism of a differentiated nerve-cell. And yet the heart is the case where the automatism of the ganglia seems clearest."

At this point we reach the parting of the ways. The long series of researches made by Gaskell and embodied in a valuable paper which has for well-nigh quarter of a century been a constant subject of study amongst all of us interested in the problem of the circulation may be regarded as the starting point of the myogenetic theory. In this admirable contribution the author enunciates two laws, as follows: "the power of independent rhythmical contraction decreases regularly as we pass from the sinus to the ventricule," so runs the first law. The second is, "the rhythmical power of each segment of the heart varies inversely as its distance from the sinus." These conclusions have never been controverted, and from an exoteric point of view there is practical unanimity regarding them. It is when we approach their esoteric consideration that we are struck by the fact that the phenomena are susceptible of explanation in two absolutely antagonistic ways. Gaskell concludes that the contractions are myogenetic and automatic, He bases his belief in the myogenetic origin of the contractions on the absence of special nerve structures, and on the fact that when the rhythm is once well established the strip can be cut into small pieces, each of which will still continue its rhythm for a long time. The origin of the movements must therefore, according to Gaskell, be either in the muscle cells or nerve fibres, as was suggested by Schiff in discussing the movements of the heart. It is to be noted that Gaskell does not deny nerve influence. By the method of its development Gaskell was led to the conclusion that the rhythm is due to some quality inherent in the muscle itself, *i.e.*, that it is automatic. He holds that nothing can be more striking than the nature of its development, the gradual recovery of conduction, the steady increase of the contraction, the uniform augmentation of excitability—all show a steady improvement in the activity of the processes upon which the various properties of the muscle depend, which is manifested by the outburst of automatic rhythmical contractions. It continues for many hours after the discontinuance of all stimulation. Gaskell points out that the ventricle contracts in due sequence with the auricle, and shows by experiment that this occurs only when such a contraction wave passes to the groove. He points out the special structure of the muscular fibres at the sino-auricular junction, forming a regular band or muscular ring from which the fibres of the auricle take their origin; and again at the auriculo-ventricular junction, where there is another well-defined ring of parallel muscular fibres from which, in part, the muscular fibres of the ventricle take their origin. The existence of these two muscular rings connecting the two muscular cavities of the heart is, according to Gaskell, amply sufficient to account for the passage of the contraction from the sinus to the auricle and from the auricle to the ventricle without the necessity of invoking the presence of ganglion cells. He next repeats the experiments of Eckhard and Marchand, which led them to conclude that the auriculo-ventricular ganglia are essential for the due sequence of the ventricular upon the auricular contractions in the frog, and he asserts that, after removing them, the sequence continues just as well as before. From a few observations upon the heart of the skate he concludes that it affords a good example of the peristaltic nature of the heart beat and also furnishes a new proof that the starting-point of the peristaltic contractions is determined by the nature of the muscular substance rather than by the presence or absence of ganglion cells.

Gaskell shows that the cardiac nerves are able to increase and diminish the conductivity of the muscular tissue of the auricle. He finds, however, and the fact is of great importance, that nervous action can remove a partial block, and that it does so because it expedites the recovery of the conduction power of the muscle. One of Gaskell's most important results is that by nervous influences there may be increase or diminution of the five different aspects of cardiac activity—

(*a*) [illegible] of the Oration delivered before the Medical Society of [illegible] 27th, 1907.

rhythmicity, excitability, conductivity, contractility, and tonicity.

The chief criticism to which the observations and deductions of Gaskell are open lies in the fact that there is in every case the presence of nerve tissue. Further, the changes in rhythmicity and the other functions which he describes as the result of experiments on the vagus seem to me strong arguments for a nervous origin of these functions.

The co-ordination of the cardiac movements and the conduction of the motor impulses is attributed by Engelmann to the muscular connections which have in recent years been described; and, to get over the difficulty of the almost instantaneous conduction of impulses through the auricles and through the ventricles while a comparatively long time elapses between their respective contractions, Engelmann ascribes with Gaskell a more restricted and embryonic power of conduction of motor stimuli to the muscular bridges. He points out that the facts of artificial stimulation in different parts of the heart show that the conduction may be reversed, and he regards this as being highly antagonistic to any theory based upon nerve conduction. Again, he points to the result of researches into the rapidity with which motor impulses pass through the heart, which are much slower than under similar circumstances in the motor and sensory nerves. From all these facts he holds that the theory of neurogenetic conduction and co-ordination is no longer tenable.

The arguments derived from the recent studies of the connections between the vein and the auricle, as well as those between the auricle and the ventricle, together with the wonderful ramifications of the Purkinje fibres, have often been claimed as strong evidence in favour of the myogenetic theory. The same is true of the clinical features of heart-block studied from the clinical point of view by a great army of physicians, and of the pathological investigation of morbid changes in the auriculo-ventricular bundle which have been described by Stengel, myself, Schmoll, Jellick, Cooper and Ophüls and Keith and Millar. But it has to be remembered that even the auriculo-ventricular bundle contains not only nerve fibres but ganglia as well, as has been shown by Tawara and Keith. That the conduction is by muscle cannot as yet be held as proved.

It is universally recognised that the seat of the causes of the rhythmic movements lies in the great veins entering the auricular sinus. From the days of Albrecht von Haller to the times of Lauder Brunton, MacWillian, Engelmann, Hering, Krehl, and Romberg, this fact has been received with general acceptance. But to what particular tissues is the function to be assigned? In one of the most beautiful researches of recent years Keith and Flack have attempted to answer this question. They describe the musculature of the sinus as being freely continuous with that of the auricular canal and auricle, and in their search for a well-differentiated system of fibres within the sinus. which might serve as a basis for the inception of the cardiac rhythm, they have been led to attach importance to a peculiar musculative surrounding the artery or arterial circle at the sino-auricular junction. The structure is described as being like that of the auriculo-ventricular bundle, consisting of an intimate network of pale undifferentiated fibres with well-marked nuclei. It is to be observed that Keith and Flack describe the presence of nerve cells and nerve fibres, and state that "although the mass by its connections is undoubtedly muscular, the nerves in the neighbourhood of the vena cava appear to come into very intimate connection with it, so that we feel justified in stating that a highly-differentiated neuro-muscular junction occurs at this point."

The occurrence of a block at the sinus, if the interpretation furnished by Hering and Wenckeback, as well as by Ritchie and myself is correct, seems to me strongly in favour of neurogenetic conduction. The muscle fibres are certainly not so much restricted as in the case of the auriculo-ventricular bundle according to Keith, and the recurrence of a block at this point is, therefore, more likely to be the result of disturbed nerve influence than of diminished muscular conductivity. This, in fact, is fully recognised in a valuable paper by Keith and Flack which appeared after these remarks had been written. They frankly acknowledge that a sino-auricular block cannot be due to any anatomical lesion of a narrow bridge of fibres, but must arise from the depression, probably of vagal origin, of the muscular tissue. We may well ask why muscular tissue?

With regard to the contractility and conductivity we must hold that as yet no evidence has been brought forward that differentiates between the muscular and the nervous fibres.

The occurrence of irregularity of the heart in early life seems to me to have an important bearing upon this subject. The long series of careful observations made by Mackenzie have led him to the conclusion that the irregularity of early life is commonly of nervous origin, and his conclusions entirely commend themselves to my judgment. This view necessarily leads to the probability that disturbances of the heart functions arising in such a way are more likely to be produced through changes in the intra-cardiac nervous system than the muscular. The irregularities of later life are undoubtedly produced very commonly by structural alterations in the muscular as well as the nervous tissues, and no argument from them can be deduced; but many of the toxic forms of arhythmia in patients suffering from gouty troubles are, like early irregularity, to be regarded as in favour of the neurogenetic theory.

The action of chemical substances has sometimes been invoked as an argument in favour of the myogenetic theory. It was shown by Biedermann more than five and twenty years ago that the skeletal muscles may show rhythmical contractions under the influence of alterations in the chemical composition of the fluid by which they are surrounded, and more recently Loeb has demonstrated that certain ions have the faculty of producing such phenomena. Here again, however, it is a pure assumption that such agents act on the purely muscular protoplasm. Seeing that the muscle cell is inextricably interwoven with nerve fibres, and that these nerve fibres, as Carlson has shown, are less subject to destructive changes than the muscle cells, the argument would seem to the unbiassed mind to lie in an entirely opposite direction.

The observations of Magnus and of Sollmann are of considerable importance in their bearing upon the question at issue. They have been able to prove that distension of the coronary arteries is able to start and to maintain the beat of the heart. It seems probable that Sollmann is correct in his conclusions that this fact is in favour of the neurogenetic theory, since it seems likely that the effect of distension is to stimulate the nerves in the walls of the vessels, whence the impulses are conveyed to the ganglia.

One most interesting fact has recently been ascertained regarding the peristalsis of the intestine in the embryo by Yanase, who has discovered that this function does not make its appearance until the development of the earliest nervous elements. Yanase concludes from his observations that the automatic movements of the fœtal intestine are neurogenetic in origin. There are undoubtedly some differences between the state of matters here and in the case of the embryonic heart, in so far as the heart beats before any nervous structures are apparent in it, while the first movements of the intestines are synchronous with the earliest development of nervous structures. The facts investigated by Yanase are, nevertheless, a powerful argument in favour of the neurogenesis of cardiac pulsations.

So far we have devoted attention to the observations and opinions in favour of the myogenetic hypothesis. It is time to turn for a space to facts and views which have been recently advanced in favour of the theory of Volkmann.

Observations upon invertebrates, even of lowly types, have been of great assistance in the elucidation of the problems connected with cardiac movements. A very large number of researches have been carried out in this field, of which it is only possible to refer to a limited number, from which the most important information has been obtained.

The obvious criticism of all investigations on the invertebrata is that the invertebrate type of heart cannot be regarded as homologous to that of the vertebrates. The organs undoubtedly differ widely in structure, and exact comparison is therefore impossible; it is, nevertheless, a striking fact that Carlson finds so many points of resemblance in the two types. It may be recalled, moreover, that Wenckebach admits there is no fundamental difference between striped and smooth muscle fibres, or between vertebrate and invertebrate muscle cells.

Amongst the opponents of the myogenetic theory Von Cyon stands prominently forward as one of the most formidable in destructive criticism. In his famous paper, "Myogen oder Neurogen," he furnishes one of the most acute examples of physiological polemics which our generation has witnessed. To this has more recently been added his work on the nerves of the heart, which also abounds in trenchant criticism. On this occasion it is impossible to follow the author through his analysis of the myogenetic hypothesis, but it may be said in a word that his opinion is strongly in favour of the views of Volkmann and his followers.

An important argument against myogenesis is to be derived from the fact that the heart may conduct impulses without manifesting contraction. Fredericq observed that the apex of the heart might be electro-negative to the base, or, in other words, that it contracted before the base. Waller and Reid found that the apex may either precede or follow the base in the manifestation of electro-negativity. Bayliss and Starling, on the other hand, found that in health the base always manifested electro-negative conditions before the apex, but that in hearts which had been damaged the apex might precede the base. Some light upon this subject has been thrown by the researches of Carlson on Limulus. He finds that the heart walls may conduct impulses without showing contraction. After soaking the heart until the condition of water-rigor appears, it is clear that the nerves can withstand the evil effects of the process better than the muscle cells, and after inducing that condition in Limulus he is able to prove that the conduction does not take place by muscle, but by nerve. He observes that analogous effects may be produced by heat, and that after the application of heat the muscle fails to respond, while the ganglion cells are still active.

After a long examination of the doctrines of Yandall Henderson, MacWilliam, Fredericq, and others, the lecturer quoted the quaint remarks of Burton on excessive mental effort as a cause of melancholy. "No labour in the world," he says, "like unto study."

The conclusion of the whole matter, so far as can be seen at present, lies in a question of probabilities. Five years ago my adhesion was almost given to the myogenetic hypothesis, but much clinical observation and pathological investigation, as well as laborious study of critical analysis of all the important contributions upon the subject, have led me to the conclusion that the view of Volkmann is still a more satisfactory explanation of the facts than any other which has yet been advanced.

Dealing with matters of such intricacy and complexity it must be frankly confessed that such proof as will satisfy the demands of a rational scepticism is still far from attainment. It is, indeed, difficult to see at the present moment whence such evidence is to be obtained.

"Causa latet, vis est notissima fontis."

Dr. Barritt, medical officer of health to the Spalding Urban District Council, in his annual report to that body, states that during the past year, out of a total number of 163 deaths, 18 had been due to cancer, as against 13 last year. This gave a percentage of 11.04 of all deaths registered.

THE OUT-PATIENTS' ROOM.

THE ROYAL EAR HOSPITAL.

(*Hereditary Syphilitic Labyrinthitis*).

By P. Macleod Yearsley, F.R.C.S.

Among the out patients was a young man, æt. 37, a clerk by occupation, who complained of deafness in both ears, with rushing and booming tinnitus. The right ear commenced to lose its function two years and a half ago, becoming deaf with moderate rapidity. The left ear became affected three months later, but not to the same extent. For the past ten days he had been totally deaf in the morning, and he stated that the hearing varied considerably during the day. Both deafness and tinnitus were always worse lying down. Fifteen years ago he had suffered for a long time with his eyes, requiring to be under treatment for some months. He had never had any vertigo.

On examination the right tympanic membrane appeared to be practically normal, the left was uniformly dull. There was no indrawing. No seriously abnormal condition was to be seen in the nose or throat, and the post-nasal space was free. The eyes showed old interstitial keratitis, the teeth were not typical.

On functional testing it was found that Rinne's test gave a positive reaction on both sides. There was loss of bone conduction for the C (128) tuning fork amounting to 29 seconds on the right side, and 24 seconds on the left. Galton's whistle registered 2.4 on the right side and 2.8 on the left, showing loss of perception for the notes in the upper scale. Owing to the noise in the Consulting Room the lower scale was not tested.

Mr. Macleod Yearsley said that the diagnosis was clearly that of hereditary syphilitic labyrinthitis. These cases were of very great interest from the pathological and otological points of view. They could be divided into two groups, both of which had their counterparts in the acquired disease. These two groups were:—

1. Deafness without vertigo.
2. Deafness with vertigo.

The first of these, in which the deafness came on with giddiness, and to which the case under consideration belonged, was by far the commoner variety. The history was usually that of a gradual onset, one ear being affected before the other, and usually the eye symptoms closely preceded the aural manifestations. As a rule, other signs of hereditary syphilis were well marked, making the diagnosis easy. It must not be forgotten, however, that the ears may become affected before the eyes. In such cases, where the congenital specific signs were ill-marked, the diagnosis must rest upon an insidious internal ear deafness coming on between the ages of 8 and 25 years, all other possible causes having been excluded.

It was to be noted that the age of the present patient was 37, and he had first shown signs of deafness at about 34 or 35. The condition had, therefore, appeared rather later than usual. Mr. Macleod Yearsley had, however, once seen it appear, in a private case, as late as 50 years of age.

Another interesting point, and one that it was, unfortunately, impossible to ascertain in this particular case, was the question of early treatment. It had been pointed out that hereditary syphilitic labyrinthine deafness only appeared in those persons in whom appropriate treatment had been neglected in infancy.

The pathology of this group of cases, in which deafness came on gradually and without vertigo, was that of a chronic osteitis, leading to a gradual and more or less complete occlusion of the cavities of the internal auditory meatus and bony labyrinth. The symptoms closely resembled those which occurred in one form of labyrinthine disease, due to tertiary, acquired syphilis, and Politzer pointed out, from published investigations, that an osseous growth from the periosteum takes place owing to chronic inflammation of the lining of the labyrinth.

Remembering that congenital syphilis may take on a typical tertiary form, as seen in the acquired disease, and as illustrated by the throat ulceration not infrequently seen in hereditary specific children, it was possible that the condition as presented in this group was a tertiary form.

The second group of cases, in which the onset of the deafness was with vertigo, was decidedly uncommon. There was one case of this variety attending the clinic, and Mr. Macleod Yearsley regretted that it was not there now for comparison. Kipp pointed out that a certain number of cases of hereditary syphilitic labyrinthitis occurred in which sudden deafness, vertigo, disturbances of equilibrium and tinnitus were complicated by interstitial keratitis and iritis. It had been suggested that an exudation into the labyrinth, corresponding to that which occurs in iritis, takes place, but this had never been proved. These cases ran an acute, subacute, or chronic course, involving the whole of the labyrinthine nerve endings, and in which the symptoms present were best accounted for by an increase of tension due to exudation, as in the eye. The resulting deafness was due, in the acute form, to an immediate destruction of the labyrinthine nerve endings by pressure, and in the subacute and chronic cases to a constantly recurring increase of tension, with changes in the exudation itself acting on the labyrinthine nerve endings. This second group had its counterpart in secondary acquired disease. As regards treatment the prognosis was a good one, provided the case was taken in hand at an early stage, as with those recurring cases in acquired syphilis; the treatment must be vigorous. Pilocarpine given by hypodermic injection was almost a specific, provided it was used sufficiently early, starting with one tenth or one-twelfth of a grain, and rapidly increasing it until one-fifth of a grain was used. It should be injected daily for a fortnight. Should it fail to bring about improvement in that period it was useless to try it further, and mercurial inunctions with large doses of iodide of Potassium and blistering over the mastoid should be employed instead. In a case recently published, Mr. Yearsley said, the latter treatment, after being persevered with for a year, succeeded in relieving the patient, who had been suffering for several months. The surgeon should not therefore despair in old standing cases until treatment has been tried for at least that period.

OPERATING THEATRES.

KING'S COLLEGE HOSPITAL.

Case of Cerebral Concussion.—Mr. Peyton Beale operated on a man, æt. about 20, who had been admitted to the hospital some eight hours previously having fallen from the top of a cart on to the road. On admission, there was a small hæmatoma just to the left of the occipital protuberance; the man's general condition was that of well-marked cerebral irritation. He was admitted and watched, and in three or four hours had all the symptoms of cerebral concussion. When Mr. Beale saw the patient his condition was the same, but symptoms of compression were evidently commencing, for his pulse-rate was getting much slower and he was gradually becoming comatose. There was well-marked paresis of the right side of the body, so, after the head had been shaved, a large scalp flap was turned up over the left Rolandic area. No fracture was visible, either immediately beneath the hæmatoma or at any other part of the exposed bone, so he was trephined over about the middle of the Rolandic area. The dura mater was exceedingly tense, and when incised the brain bulged up through it, the intra-cranial tension being evidently enormous. On passing a flat, narrow spatula in various directions between the brain and the dura mater, dark blood and clot were found in the temporal region and it seemed likely that there was a fracture of the base of the skull, which had involved the lateral sinus. There was not any active hæmorrhage progressing, so a drain was inserted between the brain and dura mater in a downward direction, and the wound dressed in the usual manner. Mr. Beale said that this was evidently one of those cases in which the fracture did not occur at the point struck; the old idea of fracture by *contre-coup* seemed now to be given up and the modern view was that the force from the point of impact was transmitted round the vault and base of the skull and, as the base was the weaker part, it was unable to withstand the strain and so fractured. It was, he thought, interesting to note that all the compression symptoms had passed off by the time the operation was completed, and when the patient recovered from the anæsthetic his symptoms were those of concussion only; in fact, he was in the same condition as he was three or four hours after admission. Mr. Beale assumed that concussion of the brain always implied more or less laceration of brain-substance; in cases which succumbed to symptoms of concussion alone there was practically always laceration of the brain found post-mortem.

GREAT NORTHERN HOSPITAL.

Extensive Fracture of the Skull.—Mr. Peyton Beale operated on a man, æt. about 30, who had been admitted in a comatose condition after a serious head injury. The patient had received a severe blow on the back of the skull from a heavy iron rail. There was a large hæmatoma occupying the whole of the back of the skull and some hæmorrhage from the back of the pharynx. He had typical symptoms of cerebral compression: respiration slow and laboured, occasionally Cheyne-Stokes's; pulse full and slow, about 20 beats to the minute; pupils dilated, the right reacting to light only slightly; paralysis of right arm and leg and complete anæsthesia. The man having been suitably prepared, a large curved incision with the convexity downwards was made on the left side of the skull and a flap of scalp about 7 ins. in length, turned up. Several fractures were at once apparent; one of them appeared as if it went right round the skull just above the level of the occipital protuberance; another passed vertically upwards over the Rolandic area. There was no depression of bone, but it could be easily levered up by means of an elevator. Cutting forceps were applied to the elevated edges, and three or four square inches of bone rapidly removed. There was no hæmorrhage between the bone and the dura mater, but on opening the latter a large amount of dark blood clot escaped. By inserting the finger, fully half a pint of this was scooped out, and it was then seen that there was very profuse hæmorrhage coming from the direction of the longitudinal sinus. Portions of the parietal bone were then freely cut away until the sinus was reached; it was then seen that the latter was torn right across, so pressure forceps were applied and gauze packed in firmly between and around them. The brain was found to be lacerated as far as it was exposed to view, and it was obvious that there was nothing more to be done, the pressure having been relieved and the hæmorrhage stopped. Mr. Beale said that in cases where the injury was so extensive the use of the trephine was too slow and tedious. A pair of cranial cutting forceps were of great service, but, of course, the best thing was an electrically driven saw. It was advisable, he thought, to remove a good deal of bone in order that the extent of the injury might be ascertained, and a ruptured sinus exposed to view, so that there might be a chance of applying pressure forceps to it. In the case he had just operated on, the laceration of the brain was so extensive that nothing beyond removing blood and clot and dealing with the ruptured sinus could be attempted.

TRANSACTIONS OF SOCIETIES.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of Obstetrics.

President.—R. D. Purefoy, M.D., F.R.C.S.I.
Sectional Secretary.—H. Jellett, M.D., F.RC.P.I.

Meeting held May 24th, 1907.

Dr. R. D. Purefoy, President of the Section, in the Chair.

Dr. **Henry Jellett** exhibited the following specimens:—(*a*) Uterus and upper two-thirds of vagina removed by Werder's method for cancer of the vagina; (*b*) remainder of vagina and inguinal glands from the same case. They were, he thought, of interest from both the operative and pathological standpoint, as cancer of the vagina was a very rare condition. The specimen had been removed from a patient, æt. 39. She stated she had menstruated regularly up to the present time, but that there had been a certain amount of leucorrhœal discharge, which had been gradually increasing. She had not suffered in any way from hæmorrhage. Her general health was good, and she had not lost weight. On examination he found, first of all, that there was a condition of the cervix somewhat resembling an erosion. It was congested, and bled when touched. On the anterior vaginal wall there were several nodules about the size of a hazel nut, extending half way down the wall, and upwards almost to the cervix, and so close that for that and other reasons he believed the case to be one of intra-cervical cancer that had grown out on to the vagina. The case was a favourable one, and he decided to perform the operation described as Werder's operation. The operation went off better than he expected, there being practically no hæmorrhage. He removed the uterus, appendages, broad ligaments, and upper two-thirds of the vagina, but did not do a very extensive para-uterine dissection, as there seemed to be no indication for it. He separated the anterior vagina wall practically down to the urethral orifice, and the posterior wall half-way down. The patient made a favourable recovery. He sent the specimen to Dr. Rowlette, who reported as follows:—

"Specimens submitted by Dr. Jellett—(*a*) Uterus and appendages, with part of vagina; (*b*) remainder of vagina, with inguinal glands.

"(*a*) *Vagina* shows ulcerating patch, about one and a half inches in diameter, situated in anterior wall. *Microscopically* this patch shows proliferating masses of epithelioid cells. In parts the cells show considerable resemblance to gland tissue, empty spaces being surrounded by proliferating masses of cells. The condition is malignant. In other parts the cells are in solid masses. The *uterus* presents a firm, white *cervix*, which on section exhibits one or two small cysts. *Microscopically the cervix* presents much fibrous tissue. The covering epithelium is regular, but covered with fibrino-purulent exudate. The glands in some parts are normal, in others dilated and cystic. The *endometrium of the body* is soft and friable. *Microscopically* it shows congestion and neurotic changes, but the glands are quite regular. One *ovary* is firm and hard, showing *microscopically* much fibrous tissue. The *other* has some small cysts.

"(*b*) Examination of the remainder of the *vagina* and the *glands* is quite negative. The *glands* are hard and firm, but do not, as far as examination shows, contain any secondary deposits of cancer."

There was no involvement of the rectum, bladder, or breasts, or of the intestinal tract, or anywhere else that caused any symptoms, or a tumour that could be felt. Such being the case, he thought it prudent to remove the remainder of the vagina and inguinal glands.

Dr. **Hastings Tweedy** said it appeared to him, from the description, to be a case of malignant disease of the vagina, pure and simple; he was therefore anxious to know why Dr. Jellett considered the removal of the uterus necessary.

Dr. **Rowlette** said the pathology of the tumour was of great interest because of its peculiar type. On first examining the vagina he had little doubt that he would find adeno-carcinoma of the body of the uterus, but on cutting the uterus and finding no primary focus of the disease he had, he thought, to conclude that it was primary in the vagina. It was possible that it was an adeno-carcinoma originating in Wolffian remains, or it might be an endothelioma.

Dr. **Jellett**, in reply, said the uterus was removed both because he believed the case to be one of intra-cervical carcinoma extending into the vagina, and because in any case of vaginal carcinoma, if the entire vagina had to be removed, it is necessary also to remove the uterus. He had previously cystoscoped the bladder and found the wall healthy.

THE REPORT OF THE ROTUNDA HOSPITAL FOR THE YEAR 1905-6. ADJOURNED DISCUSSION.

Dr. **Neil** congratulated Dr. Hastings Tweedy, the Master of the Rotunda Hospital, on the extent of the report and the work done. In the case of unavoidable hæmorrhage, he thought it would have been better to have brought down a leg and to have allowed the patient to deliver herself.

Dr. **Jellett** referred at some length to a case of concealed accidental hæmorrhage to which he had been called from the Rotunda some ten years before. He had found a patient with a pulse of anything above 120 and a uterus which had increased in size in a few hours from the umbilicus up to near the ensiform cartilage, and with the diagnosis of concealed accidental hæmorrhage on her face. He performed Porro's operation, and found the placenta floating about in the uterus, which was full of blood. At a subsequent discussion his treatment was objected to on the ground that a large number of cases of concealed accidental hæmorrhage had been successfully treated by other means. If that were so, then Porro's operation was unjustifiable, but he was of opinion that the cases referred to were in reality cases of external hæmorrhage Dr. Tweedy stated that the case in the report was the first case he had ever seen, and he, Dr. Jellett, had made out some statistics on the matter, which showed that up to the year 1896 only five cases had occurred amongst 43,000 patients in the practice of the Rotunda. He believed Dr. Tweedy's statement to be perfectly correct, that such cases were of extreme rarity, and that, considering the very severe mortality in them, it was a mistake to try to promulgate the idea that they were common, and that they were amenable to treatment suitable and excellent in the case of external accidental hæmorrhage. Dr. Tweedy had a theory that a plug in the vagina would compress the uterine arteries; that theory was susceptible of proof, as, if the uterine arteries were compressed, the child would die, and that the child did not always die was proved by a case in Dr. Tweedy's present report. If a uterus from which no blood was escaping went on increasing in size, he thought it was fallacious to suppose that a plug would make any difference, and the only thing that could be said for it was that it might bring on labour. He suggested that the condition was to all intents and purposes identical with that of internal hæmorrhage anywhere else, and consequently the correct treatment was to get to the bleeding point from above or from below and stop the hæmorrhage at its point of origin.

Professor **Alfred Smith** regretted he could find no advance in the teaching of midwifery in the report, or that the recognised methods of treatment were not set out in greater detail. As a teacher of students he would be glad to know why Dr. Tweedy altered the old-established division of ante-partum hæmorrhage. Again, he thought the results of the standard of morbidity were extremely remarkable. The Rotunda Hospital estimate made it a remarkably good standard, whereas the British Medical Association standard made it the same as last year. The question of which was the better standard was of importance to anyone estimating statistics. Then in the treatment of abortions, it was not stated what kind of active interference was resorted to. He made the criticisms with a view to eliciting greater detail for the benefit of those who, like himself, would turn to it for information and enlightenment. He congratulated Dr. Tweedy on the excellent results which had been achieved.

Sir **William Smyly** said that, while he recognised the great difficulty in compiling tables, he agreed with Professor Smith as to the advisability of having more details in regard to interference in abortion, particularly as to the number of cases in which interference was necessary, and the nature of the interference. He regarded the introduction of separate cost for infants as a matter of great importance. He had never seen a case of death from labour shock in the report before or had he met with a case. He had, however, seen two cases in which patients very nearly died without any hæmorrhage; ultimately, however, they pulled round, and so he could quite believe that there was such a thing as death from shock after labour. As to his cases of concealed accidental hæmorrhage, it was probable that there had been only one case in the house and Dr. Baggott's case in the extern maternity. If there was any external hæmorrhage at all it showed that the uterus had some resisting powers, and that therefore that case could not be put in the same class as internal hæmorrhage without any external escape. The latter showed absolute atrophy of the walls of the uterus, and inability to resist the pressure of blood. He did not see how plugging the vagina could save the life of the person in such a case. He considered that Porro's operation was the less dangerous. He wondered if the increase in the mortality of post partum-hæmorrhage was connected with the modern method of treating the third stage of labour. It showed the care that had to be exercised in watching the uterus, as there was a risk of hæmorrhage going on which they did not either see or feel.

Sir A. V. **Macan** said he would like to have the dates of cases given for easy reference. In his memory the extern cases had increased from 70 to 2,254. He thought it was a great pity that they could not refer to the same standard of morbidity as the Continental hospitals. He had no doubt that there were many cases of slight concealed hæmorrhage that were never diagnosed. In cases of post-partum hæmorrhage, any treatment that omitted opium as a stimulant was not quite up to modern views. It was not, he thought, possible, in an annual report, such as they were considering, to enter into the details of treatment in every case.

Sir **William Smyly** explained that his observations as to concealed accidental hæmorrhage applied only to severe cases.

Dr. **Spencer Sheill** said it seemed a peculiar thing to him that a patient in a healthy condition could die of labour collapse. The three cases referred to by Dr. Tweedy bore a strong resemblance to each other in respect of causation. He did not think shock was the correct term. If the normal shock of labour acted on a patient in an unhealthy condition it was not the shock that was the primary cause of death. He thought it would be better to put such cases down as death from unknown causes rather than under the ambiguous term of shock.

Dr. **Ashe** said he thought they could greatly improve their methods of giving morphia salts. There were derivatives of morphia which were not so depressing as the hydrochloride.

The **Chairman** said the occurrence of mammary abscess in the case of septicæmia was of great interest, as it was a rare accompaniment of the condition. In the other case of septicæmia it would occur to him that probably rupture of the uterus had taken place. He found it hard to understand what circumstances in a case of hydrocephalic head could have justified version. He thought it was a pity that they had not a standard of morbidity identical with the Continental for purposes of comparison. He doubted if so much benefit had followed the discarding the use of the blunt flushing curette, and douching as was expected. He agreed with the Master of the Rotunda that pubiotomy would go a long way to rendering the induction of premature labour unfashionable; but he still thought that cases would be found for a while longer in circumstances which would justify induction.

Dr. **Hastings Tweedy**, in reply, said he was not responsible for the diagnosis in cases of extern maternity. The point which Dr. Jellett had made in regard to concealed accidental hæmorrhage was a particularly good one. If he stopped the hæmorrhage in the uterine arteries the child died because he stopped the blood that went to the placenta, that was an apparently weak point in the theory; but he could say that he had never yet failed to stop hæmorrhage coming through a plug in the vagina, and he had never known of hæmorrhage pouring out over the plug. He had shown over and over again that there was no blood collected in the uterus when once the vagina was plugged. The plugging of the vagina caused a considerable amount of shock to the patient through pressing on the cervical nerves, and he regretted to say that patients often did not get better, in spite of the plugging of the vagina, even though the hæmorrhage ceased; nor had he ever had a living child born after plugging the vagina in the manner recommended as treatment for accidental hæmorrhage. He thought it was understandable how the uterine arteries could be stopped, when there was a plug pressing up with a binder pressing down the uterus. He dreaded the alternative of cutting out the uterus from a woman suffering from shock. As regards details of cases where he had glossed over a subject, it would be found that the method had been given in a former report; if the treatment had been altered in any way it would be referred to in the new report. He had been led to suppose that he had hit on an improved standard of morbidity, as it showed a high percentage when the hospital was really unhealthy, and a low percentage when the hospital was in an extremely healthy state, as in the present year. He could assure the Section that there was no more regularity among Continental authorities than in their own country. The method standardised by the British Medical Association had the merit of being simple. As regards the cases of death from labour shock, Dr. Sheill would see that Dr. Rowlette could find nothing to account for death; and, though some other condition might have produced the shock, it was the shock that killed the patient. Sometimes the retention of the placenta gave rise to profound shock quite apart from hæmorrhage. He had therefore made it a rule that the Sister should constantly take the pulse and examine the aspect of the patient while the placenta was in, and summon the Assistant-Master the moment the least change was seen, whether there was hæmorrhage or not.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Meeting held June 5th.

President, Dr. J. O. **Affleck**, in the Chair.

Dr. R. W. **Philip** showed a series of specimens from cases of poisoning by hydrochloric acid:—(1) Extensive slough of œsophagus; (2) large slough, probably gastric; (3) two large sloughs, passed per rectum.

Mr. **William Guy** read a paper on the

ADMINISTRATION OF GAS AND ETHYL CHLORIDE.

His experience extended to nearly 56,000 dental operations, and from it he elected to use gas alone in operations which could be completed in 30 seconds, gas and ether for operations which required from 1½ to 3½ minutes, and gas and ethyl chloride for operations lasting from 30 to 90 seconds. The last group comprised 90 per cent. of extractions. One of the objects of his paper was to rescue ethyl chloride from the disrepute into which it was falling in some quarters. The objections raised to ethyl chloride were the numerous fatalities which had occurred, and the unpleasant after-effects. There were now about 30 deaths on record, and some estimated the unpleasant after-effects at as high as 20 per cent. of cases. Fatalities were due to improper administration or to the use of an unstable preparation. In the speaker's opinion it was a perfectly safe anæsthetic if properly administered. The lethal properties of ethyl chloride were due to stimulation of the cardio-inhibitory centre in early anæsthesia, and to asphyxia and paralysis in the later stages. These were due, he thought, to the use of too concentrated a dose. A combination of gas and ethyl chloride was superior to ethyl chloride alone; it avoided the risk of cardiac inhibition in the early stage of anæsthesia. He had devised a special apparatus of a simple, portable nature, for administering the two. It consisted of a face piece resembling that of a Clover's apparatus, which was attached to a one gallon rubber bag through the intermediary of a three-way tube. Attached to an opening in the tube there was a glass measure graduated in cubic centimetres and into this a fixed dose (3 to 5 c.c. of ethyl chloride) was put. By simply tilting up the measure the ethyl chloride flowed into the bag. The method of administration was as follows:—The bag being full of nitrous oxide, the face piece is fitted closely over the patient's mouth, and he is allowed to breath air, the cock of the three-way tube being turned over to the valve opening. At the end of an inspiration the cock is turned over so that he breathes into the bag of nitrous oxide; then the residual air in the lungs is included along with the nitrous oxide in the bag. He is then allowed to take 5 respirations of nitrous oxide, and then the ethyl chloride is allowed to flow into the bag and the face piece is kept in position for 25 seconds. The points about the method are (1) exact dosage, there being no lint or gauze in which the ethyl chloride is poured; and (2) a definite time limit for inhalation. Given in this way great uniformity of results was obtainable; no objectionable consequences were seen; while the duration of anæsthesia, up to 90 seconds or more, was enough for most extractions. He wished it to be distinctly understood that he regarded gas and ethyl chloride as a single dose anæsthetic, and under no circumstances would he sanction repetition with a view of prolonging anæsthesia.

Mr. C. W. **CATHCART** read a paper on

"THE USE OF MASSAGE AND MOVEMENT IN THE TREATMENT OF FRACTURES."

(which will be found on page 673). In the discussion that followed, Mr. **WALLACE** said he agreed with Mr. Cathcart as to the superiority of the methods advocated; he thought, however, that they had really been in regular use for many years, and suggested that one reason why it was well not to do away with splints entirely was, that in certain cases it might give rise to an action for negligence. In a recent case he thought the verdict of the jury turned largely on the question of the use, or non-use, of a shoulder cap.

Mr. **MILES** also agreed with Mr. Cathcart, and said that in his wards the introduction of massage by the nurses had greatly improved the result of fractures. Mr. **DOWDEN** spoke of the benefits of setting fractures of the surgical neck of the femur in the abducted position. In reply Mr. **CATHCART** said his reason for bringing up the subject was because he doubted whether early movement and massage was actually as systematically carried out as his critics asserted.

Dr. J. S. **FRASER** and Dr. J. D. **COMRIE** read a paper on

"THE NASO-PHARYNX AS INFECTION CARRIER IN EPIDEMIC CEREBRO-SPINAL MENINGITIS."

Reference was first made to Dr. Jehle's views on the epidemiology of the disease as it occurs in Silesia and the Rhine coal districts. Jehle found that school epidemics were unknown, that second cases in the same house were uncommon, and that the infection did not spread in hospitals. He therefore concludes that the disease does not spread like other infectious diseases, and that children are not dangerous as infection carriers. He points out that coal mines are good incubators on account of their heat, darkness and moisture; miners make good carriers of infection on account of their liability to catarrh, accompanied by hawking and spitting. They use the same tools and drinking vessels in the mines, and consequently infect one another. On returning to their homes they infect their children. Jehle found that affected children were drawn from families the fathers of which worked in particular shafts, and that there was no intercourse between the families except through the fathers. He also found that a mine which had previously been exempt, became infected after the transference to it of miners from an infected shaft, the infection being shown by the outbreak of the disease among the miners' families. Jehle therefore supposes that mines play the same part in spreading cerebro-spinal fever as schools do in disseminating scarlatina.

Dr. **FRASER** then pointed out that seaport towns had been particularly affected by the present epidemic, and suggested that ships below decks presented conditions not unlike mines. In Leith there had been 83 cases and 53 deaths, many drawn from the neighbourhood of the docks, and from the lowest section of the population. The method of investigation was to withdraw secretion from the naso-pharynx by means of a sterilized swab. The secretion was immediately smeared over sloped blood agar or ascitic agar. During the epidemic 7 double cases have occurred, the intervals being 20 days, 14 days, 6 days, 5 days, and 3 days respectively. With regard to prophylaxis, closing schools was of little value. Contacts should be isolated and their naso-pharyngeal cavities disinfected. Since this has been done in Leith only one second case in a family has occurred.

Dr. **COMRIE** dealt with the bacteriological investigation. After referring to the characters of the meningococcus, he described the methods employed by them in identifying the organism. Subcultures were made, and stained by Gram, and also inoculation on bouillon, glucose and litmus. Serum agglutination was avoided on account of its doubtful value. The meningococcus was found in the nose in 2 out of 13 cases of meningitis, and in 10 out of 69 contacts. Of these 10, 5 were fathers, while only 15 of the whole 69 were fathers. The organism was therefore found in the nose of a much larger proportion (33 per cent.) of fathers than of other contacts (9 per cent.)—a fact which went to support Jehle's theory. Five of the 15 fathers worked on a ship in the dry dock, and on exposing Petri plates containing ascitic agar in various parts of the 'tween decks and engine room the meningococcus was found. A whole series of cases in children were traced to this focus of contagion.

Dr. **BRUCE** complimented the writers on their work, and Dr. **KER** also spoke. He thought that the incubation was not more than a few days as a rule.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

ORDINARY MEETING JUNE 13TH, 1907.

PRIESTLEY SMITH, F.R.C.S., President, in the Chair.

MR. **NETTLESHIP** communicated a genealogy in which congenital, stationary night-blindness without ophthalmoscopic changes occurred in nine consecutive generations during about 250 years. This disease, often hereditary, was less known than retinitis pigmentosa and its so-called unpigmented variety, and, unlike them, did not progress. A great part of the present case was published by Cunier nearly seventy years ago, and had been mentioned by many writers. But the nature of the disease was unknown until a year ago, when, at Mr. Nettleship's request, Professor Truc, of Montpelier, examined several living night-blind descendants, established the diagnosis, and instituted a fresh enquiry, resulting in an extension of Cunier's tables from upwards of 600 persons in seven generations, to nearly 1800 in ten generations. Only certain branches of this large tree, containing about 260 persons, bore the disease, and of this number, just one half (129), contained in 60 childships, were affected. In half the affected childships (29), the proportion of diseased to healthy agreed with the Mendelian theory; others show a near approach to agreement, and others again would conform if the dominance were supposed to have been reversed.

About a quarter of the cases seemed inconsistent with Mendelism, but incompleteness of record doubtless accounted for some of these. The disease always passed from parent to child without a break, was rather commoner in females than males, did not lead to blindness, and was not accompanied by any other defects or peculiarities. It was not due to consanguinity; there were only two first cousin and seven second cousin marriages, and only one of these nine produced night-blind children.

Mr. L. **Werner** (Dublin) showed a coloured ophthalmoscopic drawing, lantern slides, and microscopic sections of a subretinal cysticercus. The patient, a man, æt. 19, had noticed a failure of sight in the right eye for four months. The eye was normal in outward appearance, and the tension was also normal, but in the fundus, close to the optic disc, was a large spherical projection, covered by the retina, and resembling an intra-ocular tumour. It presented a transparent bluish-white appearance, with a very delicate margin in some parts. The surface was smooth, and marked with white connective tissue-like areas, and a small portion was pigmented. A remarkable feature was the presence of a deep pit in the tumour, and also an enormously dilated retinal vessel which disappeared abruptly in the growth. The diagnosis, was doubtful, and the eye was removed. On examination, it was found that the growth was an intra-retinal cyst, in which a cysticercus had been encapsuled. The animal was dead, and portions of it were found in various states of preservation, external to the capsule, chiefly in the angles between it and the retina. One well-preserved sucker was discovered, but no hooklets, The parasite evidently succeeded in escaping from the capsule, and became imprisoned in the anterior layers of the retina and died. The pit seen in the growth with the ophthalmoscope was found to be due to a mass of granulation tissue, which divided the cyst into two cavities in the sections. It extended from the posterior to the anterior wall, and by its retraction of the latter, produced a depression in it, The blood supply of the granulation tissue was derived from the dilated vessel alluded to before.

He stated that intra-retinal cysticerci were very rare, for of twenty-nine cases anatomically examined, only three were in the retina. It was a curious coincidence that this was the third time that Mr. Werner had met with bladder-worm cysts in connection with the eye, and that those were the only examples of eye affections of this nature which had ever been observed in Ireland.

Mr. **Whitehead** read notes of (*a*) a case of metastatic tumour of the choroid. A mammary tumour, which had been present two years, was removed seven years ago. Recurrence took place in the scar, and many metastatic tumours appeared in various parts of the body. Vision failed in the right eye, and after four weeks the eye became blind, and glaucoma set in. The eyeball was excised, and a flat growth found to be present in the choroid. Microscopically, the growth was found to consist of closely-packed spindle-shaped cells, with an excess of fibrous tissue between irregular groups of tumour cells. (*b*) A case of multiple cysts of the retina, associated with glaucoma. Vision had been defective in the affected eye from birth, for three months there had been complete blindness, and for two months glaucomatous symptoms were present. Examination of the eyeball after removal showed no intra-ocular growth, but numerous translucent cysts in the retina, which was not detached. These appeared to be lymphatic cysts, developed within the retina, and separating its layers. The causative association between the cysts and the glaucoma was not clear.

The weekly report of infectious diseases issued the other day by Dr. A. K. Chalmers, the Medical Officer of Health, shows a further decrease in the number of cases of cerebro-spinal fever under supervision in Glasgow. There were 104 patients under treatment, as against 110 the previous Friday, giving a reduction of six cases during the week.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

Meeting held June 7th, 1907, at the West London Hospital.

The President, Dr. **Leonard Mark**, in the Chair.

Dr. **Addinsell** read a paper, illustrated by lantern slides and photographs, on

METRITIS.

The paper dealt more particularly with the morbid anatomy and pathology of those cases of metritis considered to be due to chronic infection, especially as a result of gonorrhœa. In the intractable cases, marked by severe and exhausting hæmorrhage, hysterectomy was considered to be generally indicated.

The paper was discussed by the President, by Dr. Mansell Moullin, and by Dr. Robinson, who referred to the good results obtained by curettage followed by the application to the cavity of the uterus of pure nitric acid.

Dr. **Arthur** read a paper on

SOME ASPECTS OF X-RAY WORK;

also illustrated by lantern slides, and spoke in detail of the diagnostic value of skiagraphy in thoracic diseases, insisting on the significance of difference between the diaphragmatic excursions on the two sides, as shown by the use of the screen, in those cases of early phthisis in which no apical deposit can be demonstrated. He explained the method of taking ortho-diascopic tracings, and pointed out its extreme value in enabling the localization of inter-thoracic conditions such as abscess or tumour. An interesting account was also given of the manner in which different positions are assumed by the heart in certain circumstances of disease. A discussion followed, in which Dr. Rice Oxley and Mr. Macadam Eccles took part.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, June 16th, 1907

The Three Doses of Digitalin in Cardiac Disease.

Prof. **Huchard**, who is the greatest French authority on heart disease, recommends three methods of administering digitalin in cardiac affections. The first is a massive dose, which is also anti-systolic and diuretic. Fifty drops of the solution of crystalised digitalin (1-1,000) are given in one or two doses for one day. After 36 or 48 hours, abundant diuresis sets in; absorption of œdema and decrease of visceral congestion and elimination of chlorides follow. If the effect is not sufficient, the same dose might be repeated eight or ten days afterwards. As soon as the diuretic action ceases, which is observed by the disappearance of the œdema, and if the cardiac contraction remains weak, very small doses of digitalin should be prescribed after a fortnight, and continued two or three weeks.

The second consists in the administration of weak or sedative doses which have an effect on the palpitations and the dyspnœa of mitral disease even at its period of perfect compensation.

From five to ten drops are given for five consecutive days and repeated every three or four weeks.

The third and last is the cardio-tonic dose which exercises only a cardiac and not diuretic action, and can be continued for weeks and months with intervals of rest from time to time; three to four drops of the solution once a day are sufficient.

By following these rules laid down by Prof. Huchard no trouble nor fear need be experienced in the administration of digitalin.

Treatment of Diphtheritic Paralysis.

According to Prof. Comby, the recognised authority on children's diseases, the best treatment of paralysis of the fauces following diphtheria consists in injections of the anti-diphtheritic serum of Roux.

Every child or adult suffering from paralysis following diphtheria, recent or of old standing, slight or grave, localised or generalised, should be immediately treated by injections of serum. The injections should be made every day for five or six days according to the gravity of the cases, the doses employed being 10 to 20 cubic centimetres.

This intensive sero-therapy presents no inconvenience, and applies to every form of the disease and should be prescribed in every case, even where the diphtheria had been already treated with serum.

Prof. Cornby treated in this manner thirteen cases, and each time the cure was complete and rapid.

GERMANY.

Berlin, June 16th, 1907.

At the Medizinische Gesellschaft, Hr. E. Barth spoke on the

Functional Changes in the Vocal Organs and their Treatment.

The voice, he said, was formed by intermittent gusts of air. The various interruptions caused by closure of the glottis must be complete, but so that the vocal cords shall not be damaged by being pressed too hard together. Disturbances of the voice might be caused by organic lesions of the voice-forming apparatus, but they might be of a purely functional nature. The type of the latter was hysterical vocal paralysis, in which voluntary phonation was lost. Another form was spastic aphonia; here, also, the larynx was healthy, the patient could breathe freely and cough. This occurred in professional speakers, and arose from excessive irritation. The treatment consisted in causing people whose vocal cords closed tightly on trying to speak, to do systematically and voluntarily what they otherwise did unconsciously—that was, in making them speak in whispers, and then, with the use of the autolaryngoscope, showing them how to speak; often, also, the introduction of a sound into the larynx whilst phonating was successful, as it kept the vocal cords apart.

A third type was the paralysis of the vocal cords that came on after laryngitis, in which the cords did not gape so widely as in the hysterical form; the conditions were similar in the case of sub-glottideal tumours, even when they had been removed, when the aphonia must be looked upon as auto-suggestive.

We found a thin, piping voice, occasionally in young people with larynges quite normally developed; this was brought about by trembling movements of the cords on phonation, and was a relic of the developmental period where the development of the tensors of the larynx and of the vocal muscles did not keep equal pace with each other. By practice, for example, under an intelligent singing master, a great deal could be accomplished.

B. Fraenkel had described a voice disturbance under the name of "Mogiphonia." It was not a complete aphonia; after a time a painful feeling came on in the throat on speaking, that made further speaking impossible.

In more recent times phonasthenia had played a great part. This might have its origin either in the respiratory or in the vocal apparatus; for example, on long speaking with a raised voice, in which the vocal cords and the elevator of the larynx were immoderately taxed. Such patients must learn to speak at first in a deep voice, and also on raising it to depress the larynx, as good singers always did. In doing this, the larynx at the same time made a forward movement, and thus the air passing outwards had a straighter course as far as the velum palati, where it found the necessary resonance.

Imperfect movement of articulation might be another cause of phonasthenia.

Hr. Gutzmann pointed out that local treatment in functional vocal disturbances sometimes not only did no good, but actual harm. Imperfect inspiration might be an important cause of disturbance; many people inspired noisily, positively with a sound. They did not relax the vocal cords sufficiently, and thereby deprived them of their needed rest. Treatment must begin in learning to respire properly.

Hr. Katzenstein remarked that anæmia was a predisposing cause of functional vocal troubles; as was seen not unfrequently in music students. Perhaps another contributory cause was a thick tongue, a sloping position of the glottis, &c.

The speaking vocal asthenics were to be distinguished from the singing ones; in these, the respiratory movements were not in unison with the musculature of the larynx; this led, by excessive strain of the latter to injury of the muscles and nerves by the air passing out. The result was a proper neuritis of the recurrent nerve with pains in the neck. Grasping the neck near the larynx gave an extraordinary sensation of pressure, and confirmed the diagnosis. Here the treatment must be that of neuritis—first, complete rest, and then slow advance in voice technique.

At the 24th Congress für Innere Medizin, the subject of

Neuralgias and their Treatment

was introduced by Hr. Schultze, of Bonn. He discussed the general points of view and the new achievements regarding ætiology, pathogenesis, and pathological anatomy, symptomatology, diagnosis, and treatment. Here first of all the chemical remedies were in place; if these failed we turned to physical methods—Nægeli's "hand-gripp," the galvanic current, warmth and heat, hot-air douches, and massage, warm sand-baths, Scottish douches, stretching of perineuritic adhesions, in the use of which, however, paralysis might be developed; (3) mixed physical and chemical treatment—injections of morphine, atropine aconitine, silver nitrate, alcohol, salt, solution of osmium, methylene blue, air, water antipyrine, Schlösser's and Lang's methods. After relief of pain had been obtained, stretching. (4) Surgical operations, when they could not be avoided—resection of ganglia, plombiering with bony exit openings, tearing out of nerves (not section).

Hr. Schlösser, Munich, found that alcohol in 70 to 80 per cent. solutions brought that part of the nerve to which it was applied into a state of degeneration with absorption of its parts except the neurilemma. The greatest possible stretches of nerves were injected as centrally as possible. For avoiding injury of neighbouring parts, strong needles with blunt, straight points were used. Curved needles only in diseases of the branches of the trigeminus. In sensory nerves, repeated injections of 2 to 4 grm., in motor nerves successive injections of small quantities with addition of alcohol after five minutes, in case of mixed and energetic treatment. Improvement continued for about a year. An anæsthetic was not advisable. Unhappy accidents were pareses, also paralyses and lockjaw. Krause's operation was to be preferred on account of the more lasting results; its high mortality was against it. With repeated injections the recurrence came on later.

Hr. Lange, Leipsic, found that after injection of 75 to 150 grammes, the pain diminished at once. He recommended 1 per cent. of eucain, in an ·5 per cent. of saline solution.

Hr. Hanaw recommended dry cupping over the painful spot for ten minutes every two or three days.

AUSTRIA.

Vienna, June 16th, 1907.

French Visit.

The medical circle in Vienna are now making preparations for a visit from the medical profession of France under the leadership of Prof. Roux. The Gesellschaft has appointed a sub-committee to provide a royal reception for August 15th, on which date the guests will arrive. The object of the visit is to make an educational tour of all the Vienna institutions and exchange ideas on the various advantages and other wise in the different countries. The event is anticipated with great enthusiasm by the Viennese.

Congress for the Protection of Children.

No public movement can be made unless a congress leads the way. The first for the protection of the child in all classes of society has just been closed. Many harrowing tales were told of the miseries of the past and the difficulties of the present. Selling and buying children is still practised with impunity in Russia and the Levant. Various speakers discoursed on the law as it was and as it should be to prevent children from being abused, overworked, underfed, and ill-used. The moral and psychic condition was also considered and the law impugned. Lydia Wolfring, President of the Pestalozzi Society for the training of children discussed the abuses of children in Vienna, and neighbourhood and complained that eight days' imprisonment was the greatest punishment she had obtained for these abuses. The greatest incidence was amongst the guardians of illegitimate and step-children whose charges were unwelcome members. One of the causes of this blot is the action of the Foundling Hospital in letting out all illegitimate children to professional baby farmers. In Vienna 17,000 of these children have to be provided for annually, of whom one half die the first year.

Eczema Universale.

Leiner presented a child, six weeks old, to the members of the Gesellschaft, suffering from eczema. He has had a large number of these within a very short period and all were breast-fed children. The cause he considered was overfeeding in infants disposed to the disease which he considered as of bad prognostication for the future health of the child as statistics prove that one-third of them die.

Surgical Therapy of Puerperal Fever.

Fabricius continued the discussion of Latyko's paper on puerperal fever. He was firmly convinced that the removal of the uterus for sapræmia was a useless operation. Washing out the interior of the organ was the first and supreme duty of every accoucheur, but when the septic infection got into the lymphatic vessels and glands there was no operation left but to remove the germs surgically. Scraping the organ when thrombi and venous infection existed was not only useless but injurious. The idea of removing an infected uterus is not a novel operation, but happily it has been seldom practised. In 1895 Fabricius himself undertook one hopeful case with fatal results. Tying of the veins was another operation that he had little faith in, although he had practised it. In the case of peritonitis he had practised the radical cure since 1896. His method was to make a long abdominal incision, wash out the pus, partially close the wound, leaving it filled with gauze. He cannot agree with Latyko in performing laparotomy for incipient peritonitis as many severe cases of pelvic peritonitis terminate without any interference.

Halban thought Latyko's rule of forty-eight hours with 39 and 40 degrees of temperature rather vague to determine on an operation. He also disagreed in tying the veins for metro-phlebitis where no better results than 30 per cent. of cures could be obtained. Tying the veins in the vaginal passage was only opening a new path for thrombi which few would risk.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

Glasgow University and Medical School Appointments.—The Glasgow University Court have decided to establish a Lectureship on pathological histology, and have appointed Dr. Teacher for one year. The Governors of Anderson's College Medical School have elected Dr. John Cowan to the Chair of the Practice of Medicine at the School, in succession to Professor R. Barclay Ness, resigned.

Edinburgh Royal Infirmary.—At the weekly meeting on June 11th, the managers presented Miss F. E. Spencer, the lady superintendent, with a silver tea service and salver, on the occasion of her retirement. The plate bore the following inscription:—"Presented with a silver tea service by the members of the Board of Management of the Royal Infirmary, Edinburgh, to Miss F. E. Spencer, as a token of their high appreciation of her most efficient, valuable, and devoted services to the institution during 30 years, first as assistant superintendent, and then for the past 20 years as lady superintendent of nurses."

Complimentary Dinner to Professor Beattie.—The occasion of the meeting of the Pathological Society of Great Britain in Edinburgh last week was fittingly seized upon to entertain Dr. Beattie, who recently left the pathological department in Edinburgh University to take up his duties as Professor at Sheffield. The dinner, which was given him on June 7th, was largely attended, and was a tribute to the high esteem in which Professor Beattie is held, not only in Edinburgh, but among his colleagues generally. Dr. P. A. Young, President of the Edinburgh Australasian Club, congratulated another Colonial on being appointed to an important chair, and Professor Greenfield, in proposing the guests' health, spoke most appreciatively of his old assistant.

Professor Sir Thomas Fraser, the popular occupant of the Chair of Materia Medica, in the University of Edinburgh, has received the degree of LL.D. from the University of Cambridge. Professor Fraser's work on the Plague Commission, his high reputation as a scientist, and his position as a member of the General Medical Council have made him one of the recognised leaders of the medical profession in Scotland, and the honour which has now been bestowed on him by the Southern University is as gratifying to his colleagues and old pupils as it is flattering to the recipient.

BELFAST.

The Corporation and the Forster Green Hospital.—For several years the Belfast Corporation have been discussing the question of providing more accommodation for the treatment of consumption, but for various reasons have delayed. One reason has been the great outlay on the infectious diseases hospital at Purdysburn, and another the desire to see how the Workhouse Sanatorium at Whiteabbey succeeds, as much may be learned from its success or failure. Meantime negotiations have been going on for the extension of the work of the Forster Green Hospital for Consumption, which has ample room for increase if funds permitted. It has been arranged by the Public Health Committee to recommend to the Corporation to adopt an agreement by which they shall take twenty-five beds at a charge of 35s. per bed per week, the agreement to run for ten years, and the Corporation to have two representatives on the Board of Management of the Hospital, the Lord Mayor and the Chairman of the Public Health Committee. The reason of the long period for which the agreement is made is of course to make it worth while for the hospital authorities to provide additional accommodation, which it would not be if the agreement were a short one. It is not yet announced what arrangement has been made, or is to be made with the medical staff of the hospital, which is an honorary one. Presumably they will hardly be expected to attend the new class of patients gratuitously. It would be a most lamentable precedent if they did so.

The Health of Lurgan. In his annual report on the health of Lurgan, Dr. Agnew, the energetic medical superintendent officer of health, makes an interesting suggestion. He shows that the ravages of phthisis are very severe, and specially among young adults, and he suggests that the Town Council should acquire ground and build twenty or thirty comfortable, airy, and sanitary cottages, after the manner of the labourer's cottages built by the rural sanitary authority, which could be let at two shillings or half-a-crown a week to families in which consumption existed or threatened to break out.

Cerebro-spinal Meningitis.—The epidemic of cerebro-spinal meningitis continues to diminish. Last week there were only thirteen cases notified, and the deaths numbered ten. There are still 36 cases in the fever hospital.

Post-Graduate Work at the Royal Victoria Hospital, Belfast.—During the summer of 1907 a post-graduate course of Practical Demonstrations of cases and clinical methods will be given by the Medical staff. The course will last for a fortnight, beginning on Monday, July 1st, and terminating on Saturday, July 13th. The inclusive fee is £3 3s. The hospital contains 300 beds, and affords splendid material for clinical and post-graduate work. Practitioners who wish to attend should send their names as early as possible to the Hon. Sec., from whom any further information desired can be obtained.

LETTERS TO THE EDITOR.

THE HOSPITAL FUNDS AND THE EXCLUSION OF SCOTTISH DIPLOMATES FROM THE MAJORITY OF LONDON HOSPITALS.

To the Editor of The Medical Press and Circular.

Sir,—On behalf of the Council of the Association of Scottish Medical Diplomates, I beg to draw your attention to what we consider a grave injustice to those holding the Diploma of the Scottish Colleges. We refer to the clause in the laws of many medical charities of the metropolis making the possession of a London qualification an essential condition of election to a post on the honorary medical and surgical staffs. The effect is to make those posts a monopoly in the hands of certain London corporations. We submit that this practice inflicts a gratuitous injury upon the diplomates of the Scottish Colleges, who have obtained their legal qualifications after stringent examination. We submit that the exclusion of which we complain is contrary to the elementary grounds of justice, and that its result, if not its intention, is to swell the ranks and to increase the revenues of certain London corporations at the expense of rival colleges, of Scottish diplomates, and, as we think, of the community in general. This arbitrary practice is in our opinion a relic of class privilege absolutely out of touch with the trend of modern thoughts and ideas, and one calculated to close the door to many a fine career, and in the long run to inflict injury upon the public by narrowing the field of competition. If the London qualification be of such supreme excellence, why should their holders fear competition in the open market? Why resort to such a weapon as disqualification of all Scottish and Irish competitors?

This exclusion of Scottish diplomates from the majority of London and provincial hospital appointments has been going on for many years. Our present object, however, is to draw attention to its revival in an insidious form, and its imposition by a side issue upon two institutions that previously welcomed Scottish Diplomates to its honorary staffs. We wish to show how the Hospital Sunday and King Edward's Funds have helped, doubtless unwittingly, to bring about that injustice.

There were lately three London Orthopædic hospitals—The Royal, the City, and the National. The above-mentioned Funds have for some years pressed the policy of amalgamation upon these hospitals by every means in their power. Of these three hospitals, the Royal and the City admitted Scottish diplomates to their staffs, while the National excluded them. All three institutions are now amalgamated. It seems incredible that the Funds should have permitted the new charter of the Consolidated Hospitals to exclude Scottish diplomates. Such, however, has been the case. In other words, the National Orthopædic Hospital has been enabled to force its exclusiveness upon the other two partners in the new institution. One holder of a Scottish qualification has been allowed to join the new staff, apparently in defiance of the charter. Another member of the City Orthopædic has been denied any staff appointment in the new institution on the ground of not possessing a higher English qualification.

That gentleman naturally protested against his exclusion. To investigate the facts of the case, Sir Edmund Hay Currie was appointed arbitrator. His report stated that:—

(1) The Charter could be amended.

(2) That an exception should be made in favour of the gentleman concerned.

(3) And that the conditions as to qualification would doubtless be retained in the new charter.

We submit, Sir, that this charter in its present form is unjust, inasmuch as it excludes Scottish diplomates. We submit further that its amendment should be made to cover not only the specific hard case of a single Scottish diplomate, but to throw open all staff appointments to all registered medical practitioners.

His Majesty King Edward and the Prince of Wales are deeply interested in the two Funds which have been mainly concerned in bringing about this amalgamation scheme. We hereby appeal to them earnestly and solemnly to assist in removing an intolerable injustice from the shoulders of the Scottish diplomates. The King Edward's Fund has recently applied to Parliament for incorporation, but we venture to say the assent of the Commons is not likely to be unanimously secured if it be known that a body not amenable to public control sanctions, and in one instance has actually encouraged the exclusion of Scottish diplomates from London Hospital appointments.

We trust, Sir, that your columns will be thrown open to the discussion of a subject that, directly or indirectly, affects the interests of thousands of Scottish diplomates in various parts of the United Kingdom.

I am, Sir, yours truly,
Claude St. Aubyn-Farrer, President.
11 Chandos Street, W., May 31st, 1907.

THE CASE OF DR. HEBERT.

To the Editor of The Medical Press and Circular.

Sir,—I do not know whether any accounts of my late unfortunate experience in France have appeared in your columns; if so, or under any circumstances, I should feel obliged if you would kindly publish the result of the case, so far as I am concerned, as I am most anxious to show that I have brought no disgrace on the medical profession to which I belong and that I have been a victim instead of a guilty man. I enclose herewith a report which appeared in the *Daily Telegraph* of the 4th inst., and would esteem it a great favour if you would copy it in your journal:—

"The judicial authorities at Versailles have just announced that there is no charge whatever against Doctor Hebert, so that his character is without a stain. I had considered all along that there was no evidence whatever against him, and it seems very hard that he should have been detained so long in custody, when, moreover, he was suffering cruelly from the effects of the murderous assault perpetrated on him at Bois-le-Roi, and should have been subjected to so many unkind remarks and criticisms. The trial of Madame Guerin is now fixed to take place at the Versailles Police Court, on July 11th, and Doctor Hebert will, as is understood, lay claim to damages."

I am, Sir, yours truly,
P. Z. Hebert, M.D.
14, York Place, Portman Square, W.,
June 15th, 1907.

[We are very glad to give publicity to Dr. Hebert's letter, as so many wild and sensational accounts of the affair have been current that it has been impossible for medical men in England to arrive at the truth.—Ed.]

THE SOCIETY OF APOTHECARIES OF LONDON BILL, 1907.

To the Editor of The Medical Press and Circular.

Sir,—This Bill having been passed by both Houses of Parliament (The Medical Press and Circular

June 12th, page 661), now only awaits the Royal assent to become law. It changes the title of L. S.A. to the more appropriate one of Licentiate in Medicine and Surgery, and gives authority to the Society to confer the latter title, by diploma, on all of its Licentiates who have qualified since June 30th, 1887. Authority is also given to the General Medical Council to enter the new description on the *Medical Register*. Power is given to the Society to restore (with the consent of the Medical Council), the name of any Licentiate who may have been removed from the Roll. Heretofore, the Society had only the power to remove a name. The cost of obtaining this Act has been considerable, and the Council of the Association of Physicians and Surgeons of the Society of Apothecaries undertook to raise £250 towards it. Of this sum £222 5s. 6d. has been subscribed by the Licentiates, £25 was voted by the Association from its funds, leaving a deficit of £2 14s. 6d. The expenses of collection amount to £13 1s. 9d., bringing the total deficit to £15 16s. 3d. May I ask those Licentiates who have omitted to send a donation, to send their contributions to me without delay? It is scarcely fair that the members of the Council of the Association, who have had all the hard work, and who have already borne more than their share of the expenses should also be saddled with this deficit.

I am, Sir, yours truly,
A. Rivers-Willson.

42 Wellington Square, Oxford,
June 15th, 1907.

THE TREATMENT OF CANCER.

To the Editor of The Medical Press and Circular.

Sir,—With reference to a leading article in one of your contemporaries on June 15th, entitled "Another Cancer 'Boom'" I would ask you to allow me to point out that I cannot be responsible for treatment which is not in accordance with my original recommendations, any more than that I am responsible for the numerous references to the trypsin treatment appearing in the lay press. In no instance have I made any claim in a curative sense for the trypsin treatment of cancer, or suggested it as opposed to primary operation or to other methods of treatment.

Whatever its initial defects, limitations or value may be, I have from the first fully and freely published details of treatment, with from time to time additional aids and recommendations as they seemed to me. It is not my fault if in numerous references to the method, technique and treatment, which have been taken, so far as I can see, from my work, my recommendations have not been followed or ignored, or asserted improvements introduced.—I am, Sir, yours truly,

J. A. Shaw-Mackenzie, M.D.Lond.

London, June 17th, 1907.

OBITUARY.

JULIUS DRESCHFELD, M.D., F.R.C.P.

We regret to announce the death of Dr. Julius Dreschfeld, of Manchester, who died suddenly at Withington on Thursday night from heart failure, at over 60 years of age. Dr. Dreschfeld was a native of Niederwern, Bavaria, and was educated at Bamberg, Owens College and School of Medicine, Manchester, and Würzburg University. During the Austro-Prussian War he served as assistant surgeon in the Bavarian Army, in 1872 he became assistant physician at the Manchester Royal Infirmary, in 1873 lecturer and 1874 professor of pathology at Owens College. Latterly he held the chair of Medicine in the same college until ill-health compelled him, about a year ago, to retire. In 1886 he was Bradshaw lecturer, and among other appointments he held were those of examiner in medicine at Cambridge and at the Royal College of Physicians, of which he was a fellow. Dr. Dreschfeld was a man of great ability, and his contributions to medical literature were numerous and important. As a professor he did much to raise the tone of Owens College, and his services as a consultant were in large request in Manchester and throughout the north of England.

SPECIAL REPORTS.

LONDON COUNTY ASYLUM.

On Saturday last, June 15th, the new Long Grove Asylum, Epsom, erected by the London County Council, was opened for inspection by invitation. In 1889 the responsibility for providing asylum accommodation was transferred by the Local Government Act, 1888, from the County Justices to the London County Council, and the Asylums Committee of that body—as a statutory authority—has had the serious responsibility of coping with the task of providing accommodation for the greatly increased number of lunatics. The number of lunatics in the County of London for whom the Council was responsible to find accommodation was on the 1st January, 1890, 10,104. On the 1st January of this year the number had increased to 18,841. The increase has therefore been at the rate of over 500 a year. The asylum now completed is the tenth for the County of London and the sixth asylum erected by the London County Council. Early in the year 1903 the want of asylum accommodation became acute owing to the loss of 300 beds at Colney Hatch Asylum by the lamentable fire which occurred in January, 1903, and in order to save time it was decided to utilise a plan which had been used for two former asylums at Bexley and Horton. By the utilisation of this plan the Committee were enabled to get the sanction of the Lunacy Commissioners and the Home Secretary much more rapidly than if an entirely new design had been presented.

The entire buildings are constructed to accommodate 2,020 patients. The patients' quarters comprise wards on each side for the different classes, viz., sick and infirm, acute and refractory, epileptics and chronic, quiet and working patients—800 males and 800 females. The wards are in continuous buildings on the pavilion principle, all inter-communicating, so that the medical officers on their rounds can pass from ward to ward quickly without having to retrace their steps by returning to the main corridors before entering another ward. There are, however, main corridors communicating with each block for general service, and through these patients will pass to the recreation hall, workshops and laundry buildings. These corridors, unlike those in asylums generally, are merely covered ways, being open at the sides, and in consequence of this it is anticipated a more healthy condition will result and also a greater immunity from fire. In the main asylum are the administrative departments, the offices for the staff and quarters for the medical officers and others; also a recreation hall, 120 feet by 60 feet, with a well-equipped stage at one end and, adjoining this, a club or recreation room for the attendants and nurses when off duty. On the male side are the workshops, in which patients who are able to work are employed—tailors, shoemakers, upholsterers, also the carpenters' and plumbers' workshops, and the engineers' shops and boiler-house, where steam is generated for heating, cooking, washing, etc. Electricity for lighting and power purposes is generated at the Central Station of the Horton Estate, where the Asylums engineer has installed an electric plant sufficient for lighting three of the existing asylums on this estate. Adjoining the boiler-house is a water tower 130 feet high, in which the tanks holding 80,000 gallons of water for domestic use, and to serve as a reservoir in case of fire, the boiler chimney being incorporated in this tower.

In addition to the main asylum there are eight detached blocks or villas accommodating 400 patients; two of these for 50 patients each are designed as hospitals for the reception of new cases, where they can be medically treated and, if cured, discharged without entering the main asylum, or passed on into one of the Convalescent Homes, two of which are provided for 25 patients each, where they can be housed in a home-like way as a probationary step before being returned to their own homes. Two other villas, accommodating 65 patients each, are erected at some distance from the Asylum, for workers, one near the farm buildings for men and the other near the laundry for women. Lastly, there are two one-storey villas, each accommodating 60 quiet chronic cases, some of whom on the male side will probably work on the land, and will thus have their home in the "country" near the scene of their labours. A small Isolation Hospital for infectious cases completes the accommodation provided for patients.

A detached residence for the medical superintendent is erected away from the asylum at one end of the estate, and a detached chapel of ecclesiastical design on the south side abutting on the Horton Lane.

It will be interesting to know that the entire buildings, including all engineering work, cookery and laundry plant, lighting, telephones, etc., also the main roads on the Asylum estate, and half cost of the new road through the Horton Estate, cost of main sewer, from the Asylums, etc., to Epsom sewage farm, contribution to Epsom Urban District Council towards extension of sewage plant, airing courts, lodges, gates and fencing, together with professional charges, will come well within the estimate authorised by the London County Council and approved by the Home Secretary, viz., £514,313, it being now estimated that £490,000 will cover the entire outlay. This will show an average cost of £243 per bed on the 2,020 beds provided, accounting for everything excepting land and equipment. Mr. Thomas Hunter, L.C.C., who has been the chairman of the Building Sub-Committee from the beginning, was re-elected by the new Council.

THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AT a meeting of the Council of the College held last Thursday, Mr. HY. MORRIS, F.R.C.S., President, in the chair, a report was read from the Deputation of the Council to the Lord President of the Privy Council upon the subject of the

DIRECT REPRESENTATION OF MEMBERS ON THE COUNCIL

of the College. The deputation consisted of the President and Vice-Presidents, together with Mr. Howard Marsh, Mr. Henry T. Butlin, and Mr. Pearce Gould, who attended at the Privy Council Office on the 31st ultimo., and placed the views of the Council of the College before the Lord President.

The following alterations in the regulations for the

LICENCE IN DENTAL SURGERY

were made with a view to affording Colonial dentists greater facilities for obtaining the College diploma: "That Colonial dental practitioners who have completed a course of not less than three years' instruction in mechanical dentistry and who have been registered in British Colonies under conditions which do not require the passing of a recognised preliminary examination, be admitted to the Examination for the Licence in Dental Surgery, provided they pass the required Preliminary Examination in general education and complete the course of study required by the regulations at a recognised medical school and hospital and a recognised dental school and hospital." It was also determined that a candidate who possesses a registrable dental qualification be admissible to re-examination without producing certificate of additional study.

THE BOARD OF EXAMINERS.

The following examiners were elected for the ensuing collegiate year:—Board of Examiners in anatomy and Physiology for the Fellowship.—Anatomy: Arthur Keith, M.D., Wm. McAdam Eccles, M.S., Christopher Addison, M.D., A. H. Young, M.B.; Physiology: W. H. Thompson, M.D., G. A. Buckmaster, M.D., T. G. Brodie, M.D., C. F. Myers-Ward, Conjoint Examining Board.—Elementary Biology: T. G. Stevens, M.D., H. W. M. Tims, M.D.; Anatomy Wm. Wright, M.B., W. H. Clayton-Greene, M.B., A. Robinson, M.D.; Physiology: J. B. Leathes, M.B., B. L. Abrahams, M.B., Midwifery: A. N. Lewers, M.D., W. R. Pollock, M.D., W. W. H. Tate, M.D., H. J. M. Playfair, M.D. Public Health (Part I.): H. R. D. Spitta, M.D. (Part II.): H. T. Bulstrode, M.D.

It was resolved that, in accordance with the desire of the Royal College of Physicians, the committee of Management of the two colleges be authorised to enter into negotiations with the examining bodies with a view to securing the necessary re-arrangement of the curriculum in order to obtain two and a half years for the clinical portion. The President reported that at the meeting of Fellows to be held at the College on July 4th next for the election of four Fellows into the Council of the College, the following would be the candidates:—Mr. Herbert Wm. Page, Mr. Mansell Moullin and Mr. Frederic Eve, who seek re-election and Mr. Charles Higgens, Mr. Bruce Clarke, Mr. Charters J. Symonds and Mr. W. D. Spanton (Hanley, Staffs.), who will also be candidates for election

A letter was read from the president reporting proceedings at the recent session of the General Medical Council, and a vote of thanks was given to him for his services as the representative of the college on that Council. It was decided to close the library during the months of September and October next for the purpose of re-decoration.

REVIEWS OF BOOKS.

SURGERY BY MANY AUTHORS. (a)

THE large volume before us is the first of a series of five volumes which are in process of publication under the general editorship of Dr. William Keen who, in association with Dr. White, is already well known as a surgical author. We may say at once that the work promises to be of great value and importance, and one which will lay before the surgeon all the latest principles and practices of his art.

The first volume consists of twenty-two chapters. The first ten of these deal with general subjects related more or less intimately to surgery. Each of these chapters constitute a monograph on the subject with which it deals. Amongst them may be particularly mentioned the chapter on "Surgical Physiology," by G. W. Crile; on "Infection and Immunity," by Ludvig Hektoen; on "Inflammation," by J. G. Adami; and on the "Process of Repair," by F. C. Wood. The remaining twelve chapters are occupied by more special subjects, and of these the chief are on "The Traumatic Fevers," by Eugene A. Smith; on "Surgical Tuberculosis," by J. C. Da Costa; on "Chancroid" and "Syphilis," by E. Martin; on "Tumours," by J. Bland Sutton; and on "Wounds and Contusions," by G. W. Crile. In the last-named article an interesting account is given of the writer's experience with his "pneumatic suit," which he adopts in cases of shock as a means of raising the blood pressure.

The illustrations throughout are very good, and, save in a few cases, are new. In this respect, Mr. Bland Sutton is perhaps the greatest sinner, as a number of the illustrations which appear in his article on tumours have already appeared in other works. There are eighteen full-page plates, most of which are executed in colours.

We look forward with great interest to the publication of the subsequent volumes of this work, as, if the present high level is preserved in the different articles, it will constitute a landmark in the field of surgical literature.

ESSENTIALS OF HISTOLOGY (b).

SCHAFER'S Histology is a book with which most of us have been familiar since our student days, and which long since made its place amongst the books which the English medical student must possess. It has been considerably enlarged since its first appearance, and now attains the respectable size of over 500 pages. We have always held it to be by far the best of the existing student's manuals on the subject, and the present edition amply justifies this opinion. The text is clear, and not over-burdened with detail, though important additions have been made, which add to the completeness of the book. The author has all along recognised the supreme importance of numerous and good illustrations in teaching the subject, and in enabling the student to understand the application of what he reads to the structures which he sees under the microscope. This edition contains 553 illustrations, many of which are in colour, and almost all of which are good. The principal additions, both in text and illustrations, are in the section on the nervous system, a proper knowledge of which, as the writer very justly points out in his preface, is essential to students of medicine. We cordially recommend the book, and believe that it will long continue to preserve its present high reputation.

(a) "Surgery: Its Principles and Practice." By various authors. Edited by William Williams Keen, M.D., LL.D., Professor of the Principles of Surgery and of Clinical Surgery, Jefferson Medical College, Philadelphia. Vol. I. With 261 text-illustrations and 17 coloured plates. Pp. 983. Philadelphia: W. B. Saunders and Co. 1906.

(b) "The Essentials of Histology." For the use of Students. By E. A. Schafer, Sc.D., F.R.S. Professor of Physiology in the University of Edinburgh. London: Longmans, Green and Co. Seventh Edition. 1907.

HUMAN ANATOMY (*a*).

The book we have before us is the succeeding volume to that which we lately had the pleasure of reviewing, by Professor Sobotta and McMurrich, and it fully maintains the standard reached by its predecessor. As was remarked at that time, we regard the text as complementary to the plates, rather than the plates as illustrating the text, for by their numbers and fidelity they constitute the leading feature of this noteworthy work. Especially would we commend the illustration of the peritoneum and those of frozen sections for they are secondary only to the human body as a means of practical instruction. The verbal descriptions of the parts dealt with are of the same character as before—clear, business-like, and straightforward, but again we have to regret, speaking from the point of view of the British student, that Dr. McMurrich uses a terminology which, while it has much to commend it from a scientific standpoint, is alien to the student over here. We cannot help fearing that the use of a good many strange words may militate aginst the success of an otherwise admirable work. In general terms we have nothing but admiration for it, and we warmly commend the book to those seeking a trustworthy and graphic guide to regional anatomy.

HYPNOTISM (*b*)

"Waking Suggestion, or Psychotherapy, is a very important and proper thing, and every capable medical man must have some acquaintance with it. . . . But hypnotism is quite another matter; it is a suspicious thing, is unscientific, humbugging quackery—is, at all events, disreputable, and it is harmful and even dangerous." That, according to Professor Forel, is the official medical view, and his book is designed to make skittles of it. We may say at once that he certainly makes out as good a case for scientific and medical hypnotism as we have ever read, and although naturally a partisan, as becomes a convinced believer, the author has a clear and consistent theory and explanation for the faith that is in him. The first half of the book consists mainly of psychology, and of explanations and theories concerning the hypnotic state. These chapters are well thought out and composed, and if at times rather subtle, they are never wild. The same characteristics mark the later chapters, and we may certainly congratulate Professor Forel on his honesty in showing both sides of the case, for he indicates clearly the limitations of hypnotism and a good many of the dangers. These latter have no doubt been exaggerated, but while hypnotic influence is so little understood, it is only to be expected that very different results from those calculated for will at times accrue. For instance, in Vogt's cases of hysterical fits (p. 75), when the suggestion not to have fits only induced fresh ones, or in those of irregular defæcation where the suggestion that the habits should be regular brought on obstinate constipation. The difficulties of a subject, however, do not mean that its pursuit should be abandoned, and it is possible in the future that some reasonably stable therapeutic benefits may be derivable from the hypnotic methods. At present even some of the best and most striking of Professor Forel's cures will not satisfy the critic, either as to *post* or *propter*, though we have no doubt that they satisfy his own judgment. The most readily observable phenomenon that hypnosis should bring about is sleep, and if the hypnotist could always, or even with fair regularity, remove insomnia, his function would be established. At present all is so uncertain, vague, and unsatisfying that it is not wonderful that medical men still mistrust hypnotism. But it may safely be affirmed that their fears as to its honesty in good hands will be removed, and their interest in it awakened by the reading of this book, which, moreover, they should find uncommonly well adapted to be a source of after-dinner enjoyment. Mr. Armit has done his translating well—indeed, very well—on the whole, and he certainly deserves thanks for presenting the profession in this country with a work which is quite a standard one on the Continent.

BUILDERS OF THE BODY (*a*)

Children have some extraordinary books written for their edification, and the volume under consideration appears to us to fall into this category. We are not explicitly told that it is a child's reading book, but after a careful perusal we are forced to this conclusion. It is profusely illustrated, and sometimes it would have been better to omit the illustration. The danger of diagrammatic illustration is exemplified by the representation of a fresh cod, where the head is shown to consist entirely of proteid and salts, while the remainder of the body is labelled "water." After this it seems sinful to reject the head for edible purposes. One of the artists, whose work shows great promise, is obviously a most modest man (such modesty would not be found in the other sex), and he has felt constrained to label the articles depicted in his illustrations to show what they are intended to represent. We find that our powers of observation are developed sufficiently to enable us to differentiate between his loaf of bread and cup of cocoa without such aid. Extremely interesting is the information as to the particular foods that do not agree with Mr. Miles, and all true Scotchmen will regret that oatmeal is one of these. It must be a cause for regret to most medical men that Mr. Miles holds such perverted views on food, and wastes his talents that might otherwise be of incalculable service to the nation in propagating these ideas. Among the nonsense in this book is a large amount of valuable knowledge that would benefit a child, whose parents did not object to their offspring being taught about its "innards."

OPERATIONS UPON THE INTESTINES AND STOMACH (*b*)

The author has carried out a valuable piece of research work by an experimental study of gastro-intestinal technic on dogs and cats. In this book, which is the result of three years' work of research, are collected certain of the standard operations upon the intestines and stomach.

The importance of a work of this kind cannot be over-estimated. The author gives a description of the generally accepted methods explaining the technique with excellent illustrations, followed by the views of the various authorities supporting the different methods. Take, for example, the important question

---

(*a*) "Atlas and Text Book of Human Anatomy." By Dr. Johannes Sobotta, Professor of Anatomy in the University of Würzburg. Edited, with additions, by J. Playfair McMurrich, A.M., Ph.D., Professor of Anatomy in the University of Michigan. Vol. II. The Viscera, including the Heart. 214 Illustrations, mostly in colours. Philadelphia and London: W. B. Saunders and Co., 1906.

(*b*) "Hypnotism, or Suggestion and Psychotherapy." By Dr. (Med.) August Forel, Dr. Phil. (H.C.) et Jur. (H.C.), Chigny, Switzerland. Formerly Professor of Psychiatry, and Director of the Provincial Lunatic Asylum, Zurich. Translated from the Fifth German Edition. By H. W. Armit, M.R.C.S., L.R.C.P. London and New York: Rebman, Ltd. 1906.

(*a*) "Builders of the Body." By Eustace Miles, M.A., and Mariella John. Pp. 179 with 99 illustrations. Price 1s. 6d. London: George Philip and Son, Ltd.

(*b*) "The Technic of Operations upon the Intestines and Stomach." By Alfred H. Gould, M.D., of Boston, U.S.A. Pp. 302; 190 illustrations. W. B. Saunders and Co., Philadelphia. 1906.

of intestinal anastomosis. Here we find an account of the various suture operations, the various mechanical devices such as rings, bobbins and McGraw ligature. The advantages and disadvantages of the various methods are fully considered and pointed out; the steps of the technic are clearly explained and illustrated.

The value of the book is increased by an interesting chapter on the repair of intestinal wounds, a subject not often fully considered in books dealing with intestinal surgery. The illustrations are so clear and numerous that the book might be called an atlas.

We must congratulate the author on the important work he has added to surgical literature, and we have much pleasure in strongly recommending it to all surgeons and students interested in intestinal and gastric surgery.

LITERARY NOTES.

We are asked to announce that the forthcoming quarterly issue of *The British Journal of Tuberculosis* will be a special number devoted to children and will contain articles from British, American and German experts touching all aspects of the tuberculous problem as it concerns child life.

⁂

The sixth edition of Professor Halliburton's admirable little book on "The Essentials of Chemical Physiology" (Longmans, Green and Co.) is now out. It bears evidence of a thorough revision necessitated by the results of recent research. The book is so well known and so much appreciated that it needs no other recommendation than the testimony of the hundreds of medical students and teachers who have borne witness to its value.

⁂

Dr. J. S. Milne has now completed an illustrated monograph on "Surgical Instruments in Greek and Roman Times," which will be issued from the Oxford University Press within a few days. No clear conception of a surgical operation, ancient or modern, can be formed from a written description without some previous knowledge of the instruments, and the author points out that many interesting operations described in detail in the clinical authors, are rendered obscure or quite unintelligible from lack of such knowledge.

⁂

"The Disinfectant Value of Chlorine" is the title of a collection of reprints on the subject from the *Public Health Engineer* (price 5s nett), which is published at the offices of that paper. The contributors of the papers (which deal with the disinfection of water, sewage, sputum, etc., by means of chlorine), include such authorities on the subject as Professors Klein, Sime Woodhead, and Delepine, and other well-known bacteriologists. Where there is but little organic matter, chlorine has shown itself to be a disinfectant of wonderful efficiency, and this small volume shows both the applications and the limitations of its activity.

⁂

Professor Oppenheim has conceived the happy idea of publishing a series of letters that he had originally written to various patients. The patients were chiefly neuropathics suffering from obsessions, phobias, &c., though some cases of organic disease are also included. The author ("Letters on Psychotherapeutics." By Professor Oppenheim. Translated by Alex. Bruce, M.D., F.R.C.P.E. 1907. Pp. 60) well demonstrates how hopeless it is for the physician to succeed in his object—the curing of the patient—unless he adopts a sympathetic and understanding attitude. The little essay is one we can warmly recommend to our readers, especially so in that writings of value on this important branch of therapeutics are so scarce in this country. The author has considerable literary capacity and power of expression, to which Dr. Bruce has done full justice in his excellent translation.

⁂

We have received a well-got-up little brochure prepared by the Medical Committee of the Cheltenham Spa, which should be acceptable to medical men who are disposed to recommend their patients to be treated by their colleagues at home health-resorts, rather than by those abroad with whom they are less intimately acquainted. The brochure gives a little historical and geographical resumé of the Cheltenham country, and then proceeds to describe the various waters, a full analysis of each being set out. As there are three types of water available, namely, a Chalybeate, a soda saline, and a magnesia saline type, Cheltenham presents advantages for a wide variety of cases, and it would be much to the advantage of patients generally if medical men were *au fait* with the different indications for their use. These may be found concisely stated in "Cheltenham Spa," and we trust it may be widely read and appreciated.

⁂

A cheap and valuable series of monographs is being published in the French language by Messrs. Bailliere, of Paris; the most recently issued "L'Obésité et Son Traitement," by Dr. P. Le Noir, will be specially welcomed because the preventive and curative treatment of obesity is a matter that appeals to all classes of practitioners.. Not without reason the author insists upon the necessity of forming an opinion as to the proper physiological weight of the individual before attempting to modify the actual weight, because it is only by so doing that we can obviate damage to health as the result of our intervention. The author devotes most attention to the purely scientific aspect of the question, and in our opinion deals far too briefly with the actual treatment, which after all is what most readers desire. It is a fair synopsis of current methods, but this part of the work might advantageously be expanded. There are some useful tables of comparative age-weights and alimentary values.

⁂

A valuable paper on the smoke question is contributed to the current number of *Progress*, the new quarterly. Dr. Markel describes smoke as one of the greatest factors in the physical degeneracy of our urban population, and offers concrete facts in support of his statement. The most interesting of these facts are, perhaps, afforded by the analysis of the deposits during a fortnight on the roofs of glasshouses at Chelsea. Besides 15 per cent. by weight of a sticky oil, not less than 5½ per cent. was made up of sulphuric and hydrochloric acids. The total deposit was estimated at six tons to the square mile. The next injurious effect examined into was the deprivation of sunlight. This may be gauged by the fact that during a foggy month the hours of bright sunshine were, in London, 62; at Kew (a suburb), 222; at Eastbourne, 300. The effect upon the health of children reared in such an atmosphere needs no demonstration, whilst the influence of fog on the rate of mortality is clearly shown in the Registrar's returns. During the prevalence of fogs there is always an enormous increase in the death-rate, especially in diseases of the air-passages and lungs. The greater part of the smoke in London is the product of domestic fireplaces—the most expensive, wasteful, and unsatisfactory method of warming rooms. Most houses could be heated throughout by central apparatus with a consumption of fuel no greater than now used in two or three rooms. The coal might be of a smokeless variety, small and open fires might be provided in the living-rooms of wealthier people who demanded this luxury. The change which would of course cost in the aggregate a vast sum, might be gradually brought about. Seeing that a single day of bad fog means injury and loss to the amount of hundreds of thousands of pounds to the inhabitants, any sacrifice would seem not too great in bringing about a mitigation of evils which now return with every recurring winter season.

Weekly Summary of Medical Literature, English and Foreign.

Specially compiled for The Medical Press and Circular.

RECENT MEDICAL LITERATURE.

Elimination of Sodium Chloride.—Gennari points out that sodium chloride is only sparingly found in the fæces (*Clin. Med. Ital.*, 1906, No. 8). By the use of purgatives, however, the amount found in the fæces can be enormously increased, while a corresponding diminution of chlorides in the urine takes place. When very large quantities of chlorides are ingested moreover, either by healthy individuals or by sufferers from Bright's disease, the quantity in the fæces increases. The author believes that this effect of purgatives explains the value of such medication in cases of kidney disease, as it must aid the general dechlorinisation, which has been shown to be of so much value in diminishing the œdema and effusions into serous cavities. M.

The Iron-content of the Liver. — Castaigne has exhaustively studied the question of the iron-content of the liver (*Presse Med.*, 1906, Nos. 95 and 97). Starting from the fact that the normal liver contains a small quantity, equivalent to about .2 gramme of the metal, he has examined this organ in various diseased states. At birth he finds that a large store of iron is present, and that this gradually diminishes during the period before weaning. This store and its subsequent diminution is presumably due to the utilisation of the iron in forming hæmoglobin, during a time when the food (milk) is almost iron-free. During pregnancy also the amount of iron in the liver diminishes, due to the demands made on it for the blood of the growing fœtus; and after hæmorrhages a similar diminution takes place. The most frequent cause of an increase of the quantity in the liver appears to be blood destruction, and its storage seems to be a reserve necessary for the new formation of red cells that takes place in compensation. An increase is also found in cirrhosis and in bronzed diabetis, while in chlorosis the quantity is much lessened, probably due to diminished functional activity on the part of the liver cells. M.

Function of the Supra-Renal Capsules.—Mariani has made several observations on the function of the supra-renal glands (*Clin. Med. Ital.*, 1906, No. 8). Operating on dogs, rabbits and guinea-pigs he finds that when bilateral extirpation is practised, with an interval of some days between the operations, all the animals die with the symptoms of severe intoxication. He finds also that if the glands be destroyed *in situ*, the animals die; in these cases the cortical part shows some signs of regeneration, but not the medulla. The subcutaneous injection of cortical and medullary substance has very slight curative effect in animals who have suffered bilateral extirpation. The serum of such animals and of patients suffering from Addison's disease is highly toxic, and causes a lowering of blood pressure. This toxic effect is, however, fully neutralised by extracts of supra-renal medulla, and partially by cortical extracts. The author thinks that arterio-sclerosis of young individuals may be due to hyper-activity of the medulla, and could be treated by the serum described above. The cortical substance is very slightly toxic, whilst .5 cc. of a 10 per cent. solution of the medulla proved always fatal to rabbits weighing a kilogramme. M.

The Opsonic Index as an Aid to the Early Diagnosis of Tuberculosis.—Drs. Stewart and Ritchie report their conclusions as to the value of the opsonic index in the early diagnosis of tuberculosis (*Edin. Med. Journ.*, May, 1907, p. 435). They are as follows:—(1) A single estimation of the opsonic index is an unsatisfactory method of diagnosis, as both tuberculous and non-tuberculous cases fall within and without normal limits. Thus in eighty-two tuberculous cases, forty-one had an index within normal limits and forty-one outside; these cases including pulmonary, gland and bone tuberculosis. In forty non-tuberculous cases, eleven had an index outside the normal limits. (2) If a negative phase appears after inoculation of tuberculin the presence of tuberculosis may be diagnosed. Thus in sixty-five tuberculous cases a negative phase was observed in fifty-six, *i.e.*, in 90 per cent., while in thirteen non-tuberculosis cases no negative phase was obtained. (3) The absence of a negative phase indicates the absence of a tuberculous infection. This absence also may be regarded in a previously tubercular case as indicating complete recovery. M.

Treatment of Cerebro-Spinal Meningitis with Bier's Passive Congestion and Lumbar Puncture.—Vorschütz (*Mun. Med. Woch.*, March, 1907) gives a good review of the present state of our knowledge concerning epidemic cerebro-spinal meningitis, and recommends for treatment a combination of the use of passive congestion with frequent lumbar punctures. He performs lumbar puncture whenever the fever is high, and when there are signs of increased intra-cranial pressure. Passive congestion is applied for twenty-four hours each day by means of a rubber bandage about the neck. This should be put on first tight enough to cause moderate cyanosis of the face. The bandage should be removed during lumbar puncture. The advantages of passive congestion consist theoretically in the increased amount of bacteriocidal substances brought to bear on the inflammatory process, and the increased exudation of lymph which brings fresh leucocytes to the spot, and in combination with the lumbar puncture causes a flushing of the cerebro-spinal canal. From a practical point of view it seemed to diminish the headache and was grateful to the patient. D.

Acute Pancreatitis.—Egdahl (*Bull. Johns Hopkins Hospital*, April, 1907) has analysed 105 published cures of acute pancreatitis, with the purpose of determining the relative frequency of the different factors which have been considered to have ætiological significance. Most prominent among these is the action of gall-stones in causing a retrojection of bile into the pancreas. Bacterial invasions of various kinds from the intestines or other sources undoubtedly play an important part. Entrance of gastric juice through the ducts of the pancreas has been thought by some to occur. The action of ferments originating in the pancreas particularly the action of steapsin in the production of necrosis, has attracted much attention. Egdahl, from the results of his studies, concludes that gall-stones are probably the most common single cause of pancreatitis, occurring in 42 per cent. of the cases. Gastro intestinal disorders are the next most common causes, being present in 32 per cent., of which seventeen gave a history of alcoholism. It is probable that retrojection of bile may be caused by these intestinal disorders. The organism most commonly present is B. Col. Communis; next come the streptococcus and staphylococcus. Acute pancreatitis, may occur in a large variety of conditions of which typhoid fever, tuberculosis, trauma, syphilis, emboli, appendicitis, malaria and gastric ulcer deserve mention. D.

Pleurisy with Effusions. — Chapin (*Boston Med. Journ.*, April, 1907) reports a case of pleurisy with effusion, in which he injected intra-plurally a 2 per cent. formalin solution in glycerin. Only one injection was made, but it resulted in a cure. Other treatments, which had been employed previously, did not prevent a re-accumulation of the fluid, so that repeated tappings were necessary. D.

The Effect of Salt in the Diet.—Magnus-Levy (*Der Therapie d. Gegenwart*, April, 1907) reviews the subject of the action of salt in the diet in producing œdema in diseases of the kidney. He describes the classical experiments of Widal and Javal, who caused œdema to appear and disappear at will simply by increasing or removing the salt from the diet. It is possible, however, to have a retention of salt in the body without œdema, the salt being taken up by the cells instead of remaining in the lymph spaces. The œdema of cardiac disease is not due primarily to salt retention, but to mechanical causes, and therefore the reduction of salt cannot have such a marked effect as in nephritis. Indirectly, however, it may be advantageous by reducing the thirst and consequently the ingestion of water and the work of the heart. The effect of the exclusive milk diet in the reduction of œdema is due probably to its small salt content, 3 litres of milk containing 5 gms. sodium chloride. A mixed diet prepared without the use of salt contains even less, approximately 2 gm. After the œdema has gone it is best to continue a moderate restriction of salt, allowing about 8 gm. per day. With regard to the use of salt by the healthy, a moderate amount is probably beneficial, although many vegetarians remain healthy on a salt free diet. Excessive amounts of salt have never been known to act injuriously on a healthy person. D.

A Study of Five Hundred Cases of Pleurisy.—Fraley (*Amer. Journ. of the Med. Sciences*, May, 1907) brings together some interesting information on this subject based on a study of the cases admitted to the Pennsylvania Hospital from the year 1896 to the year 1905. The tables show that the disease is more or less prevalent at all seasons of the year, but is decidedly more frequent in the colder and wetter months. Among children, sex appears to have no influence on the incidence of the disease, but after the age of fifteen years, when the modes of life of the different sexes begin to differ, men are found to be affected four times more frequently than women. Almost three-fifths of the cases occurred in patients between twenty and forty years of age and over one-third between the ages of twenty and thirty. Fifty-two cases in the series followed croupous pneumonia, and of these 48 were empyemas; while in only 30 cases could direct evidence of tuberculosis be demonstrated ante-mortem. In three-fifths of the cases, there was a serous effusion; in one-fifth there was a purulent effusion, and in the others no effusion occurred. Large effusions were slightly more frequent on the left side than on the right. In regard to treatment by tapping some very interesting information has been obtained. In this connection only uncomplicated cases are compared, and only cases discharged as cured are considered. From such cases taken as a series it appears that "uncomplicated cases of serous effusions aspirated recovered in three weeks, whereas another week was necessary to effect a cure in the non-aspirated." The contrast was more marked in the case of small effusions than in those of moderate size. In the massive effusions the contrast is afforded by those patients who refused operation, and it was found that the average duration of treatment of those aspirated was 24.7 days as against 55 days in the non-aspirated cases. Among the empyema cases the mortality was 22 per cent. for the entire series, but only 17 per cent. for those resected as against 40 per cent. for those not resected. In the cases in which simple incision and drainage was performed the mortality was 27 per cent. K.

Heart-Block.—Butler (*Amer. Journ. of the Med. Sciences*, May, 1907) records a typical case of this condition which ended fatally in ten days. The patient, a man, æt. 43, had had a slow pulse ever since an attack of typhoid fever some twenty years before his death, and it is recorded that during an attack of croupous pneumonia which occurred some two y before his death his pulse never rose above 42 minute. At the autopsy slight mitral insufficie and thickening at the base of the mitral cusps w discovered, and considerable fatty degeneration the myocardium. Microscopic sections of the bur of His showed that it was infiltrated with fat and undergone fatty degeneration to such an extent t it was atrophied to not more than one-fifth of normal size. K

Treatment of Gonorrhœa. — French (*R.A.M Journ.*, June, 1907, discusses the treatment of disease among soldiers. He is of opinion that view put forward by Major Pollock in the final Rep of the Advisory Board on the treatment of vener diseases is not correct; and that irrigation in initial acute stage of gonorrhœa is more likely cause than to prevent infection of the posterior ureth French is of opinion that during the acute stage of disease, the patient should be kept strictly in bed a treated with a light farinaceous diet, a daily sal purge, and an alkaline mixture every four hours. injection is to be permitted till the thick yellow pu lent discharge has become thinner, whiter, and m muco-purulent. After this period, the patient allowed to get up, a more liberal diet is given, a anterior irrigation is commenced with a luke-wa solution of two grains of permanganate of potassiu to the pint of water. The treatment should exte over a period of at least six weeks, and the patie should not be allowed to leave hospital as long as a gonococci can be demonstrated in the urine. F the satisfactory treatment of chronic gleet the use a urethrascope is almost essential. By means of th instrument the "granular patch," which is so com monly the cause of the discharge, can be seen, an is to be treated by the local application of a stro solution of nitrate of silver (20 or 30 grains to th ounce). The occurrence of any complication such a cystitis or epididymitis is to be looked on as an abso lute indication for stopping all active treatment the urethra, and for returning to the sedative treat ment adopted in the initial stage of the disease. K.

Carbolic Acid Gangrene.—Wallace (*British Medica Journal*, May 11th, 1907) reports nine cases of gangrene of fingers due to carbolic acid dressings. Probably pure liquid carbolic was used in at least two cases, and a strong solution in two others, but in at least four cases the preparation used was not more than 5 per cent. In none was a waterproof covering used. In none was tight bandaging a possible cause of gangrene. In every case the original injury or sepsis was at most trivial in degree. In two cases gangrene was limited to a part proximal to healthy tissue. The appearance of the gangrenous part is characteristic. The skin is at first dry, wrinkled, and greyish-white in colour; later it becomes darker and more shrivelled. At the junction of the living and dead tissue there is some hyperæmia. As it is difficult to tell how much is actually destroyed, it is proper to wait for a line of demarcation before amputation is performed. In no case was swelling of the proximal part observed. The condition is, as a rule, similar to a typical case of dry gangrene. S.

An Important Action against Dental Companies.

During the past week a case of great importance not alone to the dental, but also to the medical profession has been at hearing in the Dublin Courts.—The Attorney-General at the instance of Mr. Kevin O'Duffy, Secretary of the Irish Dental Association. *v.* Myddleton, Ltd., a limited liability company which practises dentistry in Belfast. The action was brought at the instance of the Irish Dental Association for an injunction restraining the defendants, who carry on business in Belfast and other towns in the north of Ireland, from carrying on business under the style and title of "Surgeon Dentists," and thereby infringing the provisions of the Dental Act. The defendants denied that they had been guilty of any illegality. The arguments in the case have been concluded, and the Court has reserved judgment.

Medical News in Brief.

Royal Society of Medicine.

For nearly a hundred years there have been movements in the medical profession for a union of the societies which concern themselves with the various aspects of medical practice. Some two years ago Sir Richard Powell once more raised this ancient topic. Since then negotiations have been continually in progress, and, these negotiations have resulted in the formation of a Royal Society of Medicine, which was formally constituted at a meeting of the Fellows held on June 14th at 20 Hanover Square. The Societies represented were the following: Royal Medical and Chirurgical Society, Pathological Society of London, Epidemiological Society, Odontological Society of Great Britain, Obstetrical Society of London, Clinical Society of London, Dermatological Society of London, British Gynæcological Society, Neurological Society; British Laryngological, Rhinological and Otological Association; Laryngological Society of London, Dermatological Society of Great Britain and Ireland, Otological Society of Great Britain and Ireland, British Electro-therapeutic Society, and Therapeutical Society. The committee of representatives of the societies which had indicated their adhesion to the project have drawn up a series of bye-laws, which were adopted at yesterday's meeting. They provided, among other things, for the establishment of the following sections: Clinical, Dermatological, Electro-Therapeutical, Epidemiological, Laryngological, Medical, Neurological, Obstetrical and Gynæcological, Odontological, Otological, Pathological, Surgical and Therapeutical and Pharmacological.

Sir William Church was elected the first president, and the officers and councils were appointed as follows: Dr. F. H. Champneys and Mr. A. Pearce Gould, M.S., honorary treasurers; Mr. Rickman J. Godlee, Dr. Henry Head, and Dr. Norman Moore, honorary librarians; Dr. Arthur Latham, and Mr. Herbert S. Pendlebury, honorary secretaries; and Sir Richard Douglas Powell (President of the Royal College of Physicians), Mr. Henry Morris (President of the Royal College of Surgeons), Mr. J. Warrington Haward, Mr. G. H. Makins, Sir Shirley F. Murphy, Mr. Thomas Lawrence Read, Sir Felix Semon, Dr. Frederick Taylor, and Dr. Thomas J. Walker, members of council.

The speakers at Friday's meeting included Sir Richard Powell, Sir William Church, Sir Thomas Smith, Sir Thomas Barlow, Dr. Barlow, Professor Osler, Dr. Pye Smith, Mr. Henry Morris and Mr. Clinton Dent. The opinion was unanimous that great advantage will result from the establishment of this Royal Society of Medicine. Not only will the special objects of research of each of the amalgamated societies be preserved, but the result of such a joining of forces will tend to the establishment of more comprehensive libraries, the collection of documents bearing on medical research and jurisprudence, and incidentally much economy in administration.

Apothecaries' Hall of Ireland.

At a general meeting of the members of the Apothecaries' Company, held at 40 Mary Street, Dublin, on June 7th, Dr. Seymour Stritch, J.P., in the chair, it was proposed by Dr. Montgomery, seconded by Dr. Finucane, and passed unanimously—"That the best thanks of the Company are hereby tendered to Colonel Adye-Curran, M.D., F.R.C.S., for his untiring and successful efforts on behalf of this Hall in the General Medical Council."

Ambulance Contest in the Rhondda.

The second annual competition for Sir Charles Warren's ambulance challenge shield for the Rhondda and other prizes took place at Ferndale on June 8th. As indicative of the strides made in ambulance work in a short space of time, it may be mentioned that, whilst not many months ago those capable of rendering first-aid to their comrades who might be the victims of accidents at the collieries were few, at present almost every colliery can soon turn out a squad of efficient ambulance men. All the arrangements, which had been made with thoroughness by Mr. Tom Davies, the chief superintendent of the Rhondda Fawr Corps. The attendance included a large number of medical men and colliery officials from all parts of the Rhondda, as well as the following distinguished officers of the St. John's Ambulance Brigade:—Colonel Sir Herbert C. Porrott, C.B., London (who, in the absence and on behalf of General Sir Charles Warren, presented the shield to the winning team); Surgeon-colonel E. Cureton, V.D., M.D., deputy-commissioner No. 7 District; Surgeon-lieutenant-colonel J. D. Lloyd, Chirk, district chief-surgeon No. 3 District, &c.

Colonel W. D. Steel, V.D., M.D., Abergavenny and Mr. J. H. Woolston, Worcester, the assistant-commissioner, acted as judges. The teams entered the lists in the following order:—Ferndale (the shield-holders), Mardy, Tynybedw, Great Western, Ystrad-Rhondda, Llwynypia, and Treherbert, whilst the awards were made as follows by Colonel Steel:—

First prize (shield and money prize), Mardy, 185 points.

Second prize, Ystrad-Rhondda, 167 points.

Third prize, Ferndale, 153 points.

Fourth prize, Llwynypia, 141 points.

Departmental Committee on the London Ambulance Service.

The committee appointed by the Secretary of State for the Home Department to inquire as to the ambulance provision for dealing with cases of accident and illness in the streets and public places in the metropolis, met at the Home Office on Friday, Sir Kenelm Digby (chairman) presiding. Evidence was given by Dr. Arthur W. James, honorary secretary of the Metropolitan Street Ambulance Association, and by Mr. T. Duncombe Mann, clerk to the Metropolitan Asylums Board.

The Red Cross Conference.

The eighth International Red Cross Conference came to an end on the 15th inst. The Marquis de Vogüé (France), one of the vice-presidents, took the chair in the Examination Hall, Victoria Embankment. Colonel William C. Sanger (U.S.A.) offered the hospitality of the United States to the next Conference if it should not be found possible to accept that of Japan on account of the remoteness of that country. Dr. Ferrière (France) read a report on the awards of the Marie Feodorowna prizes, which are given out of a fund established by the Dowager Empress of Russia. A cordial vote of thanks was carried to the Marquis de Vogüé, who had presided over the Conference with marked tact and ability. In the afternoon of the 15th inst. the King and Queen received at Buckingham Palace the delegates of the International Red Cross Conference, together with a number of the presidents of the British Red Cross Society, nearly all of whom were the wives of Lords Lieutenant. Altogether there were about 300 guests, including Lord Rothschild, Lord Londonderry, the Duchess of Montrose, Georgiana Lady Dudley, Lord Roberts, Sir William Butler, Lady Lansdowne, Lord Knutsford, Sir Frederick Treves, and the President of the Royal College of Surgeons. The company were received in the Picture Gallery. The presentees were marshalled by officials of the Lord Chamberlain's department, and afterwards passed in turn before their Majesties. The less formal method of greeting took place subsequently as their Majesties moved about among the assembled guests. Tea was afterwards served in the State dining-room. Baron Ozawa, the chief Japanese delegate, was the bearer of a message from the Emperor and Empress of Japan, in which their Majesties acknowledged the great humanitarian work of Queen Alexandra, especially with reference to the Red Cross League, and stated that the Empress intended to follow the Queen's example. The Queen replied to the effect that she was very much touched by the message, and desired that her greetings should be conveyed to the Empress.

NOTICES TO CORRESPONDENTS, &c.

☞ **CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessary for publication but as evidence of identity.

FUNDUS.—Successful transplantation of the cornea has only been reported once, we believe, viz., by Herr Zirm at the Vienna Medical Society. The patient's eyes had been damaged by lime, and the grafts were taken from a healthy eye removed from another patient because of a wound. Both corneæ were grafted, but only one was successful.

THE RULING PASSION.

One of the witnesses at the Derbyshire Summer Assizes related a most terrifying experience he had recently undergone. While asleep in a Welsh hotel he was awakened by heavy footfalls in the room. An individual struck a match, lighted the gas, and approached the bed Seizing his hand and feeling his pulse, and then tapping his chest, the mysterious visitor solemnly said: "You have a most serious attack of pneumonia. You may possibly live seven days, but no more." Later on the landlord explained that he had a son seriously ill in another bed. The nocturnal visitor was a doctor who had mistaken his patient.—*Daily News*.

BARBER-SURGEON.—Perhaps the best instance of the factotum doctor we can give you for your lecture is the following, which appeared in an Elizabethan newspaper:—"Wanted—In a family who have bad health, a sober and steady person in the capacity of doctor and surgeon. He must occasionally act as butler and dress hair and wigs. He will be required sometimes to read prayers and preach a sermon every Sunday. A good salary will be given."

CHILDREN'S HOSPITALS.

We are sometimes asked by men recently qualified how to set about obtaining appointments at a children's hospital. There can be no doubt that, as a subsequent introduction to general practice, a resident appointment in an institution of this nature is of inestimable value. One such is advertised in our present number, viz., a house surgeoncy at the largest hospital for sick children in the United Kingdom, for particulars of application and appointment for which we refer our readers to the Index on page iv.

M. S. P.—The figures for industrial poisoning and anthrax show a distinct decline for the first four months of this year, viz.: 161 cases with 14 deaths, against 225 cases with 23 deaths in the corresponding period of last year. In addition there were 47 cases of lead poisoning with 13 deaths among house painters and plumbers for the same period, against 52 cases with the same number of deaths in the first four months of 1906.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, JUNE 19th.

ROYAL METEOROLOGICAL SOCIETY (70 Victoria Street, Westminster, S.W.).—4.30 p.m.: Exhibition of "Step" Anemometer by Mr. W. Child. Papers:—Mr. F. C. Bayard: Weather and Crops, 1891-1906.—Mr. C. P. Hooker: The Relation of the Rainfall to the Depth of Water in a Well at Cirencester, 1903-1906.

ROYAL MICROSCOPICAL SOCIETY (20 Hanover Square, W.).—8 p.m.: Paper:—Mr. E. M. Nelson: Eye-pieces for the Microscope. Lecture:—Mr. F. Enock: The Life History of the Tiger Beetle (Cicindela campestris) (illustrated by lantern slides).

ROYAL MEDICAL AND CHIRURGICAL SOCIETY (20, Hanover Square, W.).—5.30 p.m.: Mr. D'Arcy Power: Dr. Walter Bayley and his Works, 1529-92. (There will also be a number of exhibits of medical and antiquarian interest.)

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—Cliniques:—2.30 p.m.: Skin (Dr. Meachen), Eye (Mr. Brooks), Medical Outpatient (Dr. Whipham).

THURSDAY, JUNE 20th.

ROYAL COLLEGE OF PHYSICIANS OF LONDON (Pall Mall East).—5 p.m.: Croonian Lecture:—Dr. W. J. R. Simpson: Plague.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Gynæcological Operations (Dr. Giles). Cliniques:— Medical Out-patient (Dr. Whiting), Surgical Out-patient (Mr. Carson). 3 p.m.: Medical In-patient (Dr. Chappel). 4.30 p.m.: Special Demonstration of Cases of Children's Disease (Dr. T. R. Whipham).

HOSPITAL FOR SICK CHILDREN (Great Ormond Street, W.C.).—4 p.m.: Lecture:—Mr. Kellock: Affections at and about the Umbilicus.

FRIDAY, JUNE 21st.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—9.30 a.m.: Clinique: —Surgical Out-patient (Mr. H. Evans). 2.30 p.m.: Surgical Operations (Mr. Edmunds). Cliniques:—Medical Out-patient (Dr. Auld), Eye (Mr. Brooks). 3 p.m.: Medical In-patient (Dr. Leslie).

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Mr. C. A. Parker: Clinique. (Throat.)

Vacancies.

Bradford Royal Infirmary.—Resident Surgical Officer. Salary £150 per annum. Applications to J. J. Barron, Secretary.

London County Asylum, Horton, Epsom.—Fifth Assistant Medical Officer. Salary £150 a year, with board, furnished apartments, and washing. Applications to H. F. Keene, Asylums Committee Office, 6, Waterloo Place, S.W.

Oldham Union.—Resident Medical Officer. Salary £150 per annum, together with furnished residence, coal, gas, rations, washing, and attendance. Applications to Horace A. Quarmby, Clerk to the Guardians, Union Clerk's Office, Rochdale Road, Oldham.

General Post Office—Medical Department (Male Staff).—Assistant to the Medical Officers at Headquarters. Salary £300 a year. Applications to the Secretary, General Post Office.

Egypt.—Sub-Inspector of Ophthalmic Hospitals. Salary £500 a year. Applications to A. F. MacCallan, Esq., 32, Bedford Gardens, Kensington, W.

West Bromwich District Hospital.—Senior House Surgeon. Salary £110 per annum, with board, residence, and laundry. Applications to T. Foley Bache, Esq., Churchill House, West Bromwich.

Canterbury City Asylum.—Assistant Medical Officer. Salary £140 per annum, with furnished apartments, board, and laundry. Applications to Medical Superintendent.

The University of Sheffield.—Demonstrator in Physiology. Salary £150 per annum. Applications to W. M. Gibbons, Registrar.

Newcastle-on-Tyne Dispensary.—Visiting Medical Assistant. Salary £160 per annum. Applications to the Honorary Secretary, Joseph Carr, Chartered Accountant, 26, Mosley Street, Newcastle-on-Tyne.

Newcastle-upon-Tyne.—Assistant Medical Officer of Health. Salary £300 per annum, with board, lodging, etc. Applications to the Medical Officer of Health, Town Hall, Newcastle-upon-Tyne.

Fermanagh County Hospital.—House Surgeon, salary £52 per annum.—Applications to C. Wilson, Secretary. (See advt.)

Battersea General Hospital (anti-vivisection).—Honorary Surgeon to the Eye, Throat and Ear Department.—Apply Secretary. (See advt.)

Appointments.

CALTHROP, LIONEL C. E., M.B.Durh., M.R.C.S., L.R.C.P., Medical Superintendent of Woodhall Spa, Lincolnshire.

DAWSON, GEORGE W., F.R.C.S. Irel., D.P.H., Surgeon to St. John's Hospital for Diseases of the Skin, Leicester Square, W.C.

FAIRCLOUGH, W. A., M.B., Ch.B.N.Z., House Surgeon at the Royal Westminster Ophthalmic Hospital.

FIELD, F. E., M.B., Ch.B. Edin., Clinical Assistant at St. John's Hospital for Diseases of the Skin, Leicester Square, W.C.

HARE, T. G., M.D. Freib., Pathologist and Bacteriologist to St. John's Hospital for Diseases of the Skin, Leicester Square, W.C.

HOLLICK, BERNARD SEPTIMUS, L.R.C.P. Lond., M.R.C.S., Medical Officer of Health for the Sturminster (Dorset) Rural District Council.

KELYNACK, T. N., M.D. Vict., M.R.C.P. Lond., Honorary Physician and Medical Adviser to the Children's Home and Orphanage (London and nine country branches).

RICHARDSON, M. J., M.B., M.S. Edin., Certifying Surgeon under the Factory and Workshop Act for the Wolston District of the county of Warwick.

Births.

CHAPPEL.—On June 13th, at Lansdowne House, Tottenham, the wife of George P. Chappel, M.D., of a daughter.

GERVIS.—On June 14th, at Hurdis House, Seaford, Sussex, the wife of Charles Berkeley Gervis, M.D., of a daughter.

HIGHAM.—On June 11th, at Murree, Punjab, India, the wife of Lieut. Bernard Higham, I.M.S., of a son. (By cable.)

POOLE.—On June 11th, at Hampton, South Teddington, the wife of J. C. Poole, M.R.C.S., of a daughter.

Marriages.

GROVES—MILLER.—On June 12th, at St. Mary's Church, Speenhamland, Newbury, Charles Nixon Groves, M.A., M.D., Oxon., only son of the late Charles Groves, to Frances Minnie, younger, daughter of Frederick Montague Miller, J.P., M.R.C.S., L.R.C.P., of Northolme, Upper Clapton, London.

ROBERTS—HOBDAY.—On June 8th, at Holy Innocents' Church, Hornsey, John Thomas Roberts, L.R.C.P.Edin., Meadow Lodge, Park Road, Crouch End, to Mabel Caroline, fourth daughter of H. T. Hobday, Esq., "Bougaree," Manley, Sydney, N.S.W. Australian papers, please copy.

TAYLOR—CLAY.—On June 11th, at the Parish Church, Dewsbury, Henry Percy Taylor, only son of Henry Taylor, of Whitehaven and Wakefield, to Norah, second daughter of Charles Clay, M.R.C.S., The Manor House, Dewsbury.

Deaths.

COATES.—On Sunday, June 16th, at The Hill, Laverstock, Salisbury, Harcourt Coates, M.R.C.S.E., L.R.C.P.Lond., aged 54. For 21 years hon. surgeon Salisbury Infirmary.

DRESCHFELD.—On June 13th (suddenly), at Stanley House, Withington, Manchester, Julius Dreschfeld, M.D., F.R.C.P., B.Sc., aged 61 years.

LANE.—On June 12th, at 19 Priory Street, Cheltenham, Brigade-Surgeon Benjamin Lane, late A.M.S., eldest son of William Lane, M.D., of Limavady, Co. Derry, aged 80 years.

STRAHAN.—On June 8th, at Dalbrack, Glenesk, Forfarshire, suddenly, Alexander Bannerman Strahan, Lieut.-Colonel I.M.S., Retired, in his sixty-fifth year.

VOL. CXXXIV. WEDNESDAY, JUNE 26, 1907. No. 26

NOTES AND COMMENTS.

Principles of Provident Medical Associations

AT a successful Conference held at Norwich early this month the Charity Organisation Society got up a debate on Provident Medical Associations in which many lay and medical men interested in the question took part. It is satisfactory indeed to record that although there was naturally a good deal of difference in detail, the speakers seemed generally to be in agreement as to the main principles on which such associations should be founded. These, of course, are that all medical men in a town should have the opportunity, after a short probationary residence, of being on the staff, that the members be free to choose and change their medical attendants, that a reasonable wage-limit be enforced, and that the management be wholly or in the most part in the hands of the profession. It is on the two last points that the non-medical man usually comes into conflict with the medical man, for either it is wished to strengthen the society by bringing in well-to-do people who can well afford to pay medical fees, or there is some lay person or persons who wish to "boss" the show themselves, if not actually to profit financially. Now it is obvious that as provident medical associations cater only for the poorest classes, families earning less than thirty shillings a week, the margin of profit to the medical men is small and precarious enough in all conscience, especially as the management and collection expenses have to be paid. There is no room for another slice to go into the pocket of anyone else. The Conference seemed generally to see the force of these points, Mr. Fred Henderson, the socialist, only objecting on the ground that as the worker cannot afford to pay adequately for medical attendance, a free public medical service should be available for everyone who chooses to use it.

And their Application.

COLONEL MONTEFIORE, who opened the discussion in an excellent speech, dwelt at some length on the organisation of such public medical services in connection with hospitals, dispensaries, and other charitable agencies, and gave some striking figures as to the extent to which charitable medical relief prevails. He quoted a statement that in greater London no less than 1 in 2·2 of the population is in receipt of free medical attendance, and showed that in London 1,859,809 out-patients and casualties had been treated in London hospitals in 1905. Now appalling as these figures are, and disgraceful as they are to the civilisation that makes them possible, it is not in doubt that the vast bulk of these people are needy workers to whom adequate medical fees are impossible, so that it is clear that only by the most careful organisation can it even be expected that the profession shall earn anything like a just reward from them. The machinery by which such organisation may be brought about appears to lie ready to hand in the "Metropolitan Provident Medical Association," which already has twenty-one dispensaries and thirty thousand beneficiaries in London, but in order for this consummation to come about, all the present free dispensaries should be brought into line, and the hospitals be enlisted to work in co-operation, so that nothing but consultations and casualties be carried on in the out-patients departments, whilst the beds themselves are ear-marked for association members. It is, however, a great thing that a number of philanthropic gentlemen are now beginning to see eye to eye with the profession in this matter, and though doubtless a long evolutionary period will have to be gone through, there does seem to be hope of order eventually coming out of chaos.

Doctors and Alcohol.

UNDER the title of "Doctors and Alcohol," the *Licensing World* is sending out far and wide a circular in praise of moderate drinking, and needless to say the unfortunate manifesto sent to the *Lancet* last March forms part of the propaganda, several of the most telling sentences in connection with it being printed in leaded type. There is also a reference to the *Hospital*, in which are quoted some remarks by Dr. Savage, made in his recent Lumleian lectures, throwing doubt upon the relationship between the increase in insanity and the consumption of alcohol, and further some weird statements from a paper by Dr. Haydn Brown in the *General Practitioner*, from which we gather such gems as that were alcohol forbidden by law "the death-rate would increase to an appalling extent," and "many people would soon die were it not for the stimulants they take at meal times." Now within the ranks of a liberal profession such as medicine it is not only probable, but almost inevitable, that every kind of opinion should find a representative somewhere, so that it is always possible to get some medical authority for almost any view of life, but the bulk of the profession, though it takes a certain quantity of alcohol with meals and prescribes the drug for patients in certain cases cannot but view with disfavour the exploitation of its opinion, or even the opinion of some of its members, for the purpose of pushing the sale of alcohol in general. The difficulty is not in getting men to buy drink, but to stop them buying too much of it.

Science and the Indian Government. IN *Nature* Professor Ronald Ross has a stinging article on the want of science in general administration, the Indian Government especially coming in for his castigation though the tergiversations of home governments, swayed as they are by the exigencies of party warfare, by no means escape stricture. While we recognise the Titanic task that a handful of European officials have to cope with in governing the three hundred millions of India, we would think that the advantages scientific methods offer would be all the more eagerly seized on that account, but Professor Ross, though admitting a small improvement of late years, shows how the paralysing influences of routine crush enterprise and ideas. He tells again the tale of malaria; how for fifteen years after Laveran's discovery official India took no notice of it, and how when he himself set to work vigorously at the subject of transmission every kind of official difficulty was thrown in his way. The story of cholera, of plague, and of vaccine obtained from variolisation of the calf are much the same, and the story of typhoid but little better. Knowledge has been offered to the Government, and it has either been frowned upon or treated with sparse courtesy And yet the problem of India is so indissolubly bound up with the prevalence of these diseases that its economic administration may be considered almost a department of epidemiology. Well, a change is gradually coming, so Professor Ross says, for whereas in former years not a thousandth part of the medical budget was spent on investigation, now about one-hundredth is; but even that amount is pitiably small.

Sir Frederick Treves and the Public. SINCE his successful operation on the King and his subsequent abandonment of practice, Sir Frederick Treves has become the Sir Oracle of medicine to the public, and he seems to fill their medical horizon with the almost same completeness that Lord Rosebery does their social one. Both orators have the same happy knack of emphatic and picturesque statement which arrests attention and influences opinion. Some three weeks ago Sir Frederick delivered a speech at Preston which created such a stir that the echoes are still ringing throughout the country. Two views he put forward one would have thought so nigh commonplaces as to have amounted almost to platitudes, namely, that with proper education and care fever hospitals would lag superfluous on the stage, and secondly, that the bottles on the doctor's shelf are melting away before fresh air, good food, and bright sunlight; but judging from the astonishment these "remarkable statements" have created, they might almost be classed with the utterances of Elijah or the Delphic oracle. The real lesson the phenomenon conveys is that the public are still sitting in terribly sanitary darkness, and that they are really hungering for good teaching, wherefore we hope that Sir Frederick Treves may continue his beneficent mission till people are surprised into a little common-sense on medical subjects.

LEADING ARTICLES.

THE MEDICAL INSPECTION OF SCHOOL CHILDREN.

THE necessity of the systematic medical inspection of school children has been formally recognised by the legislature of the United Kingdom. The present Government, in their Education Bill of 1906, accepted the permissive clause introduced by the President of the Board of Education. The Commons, however, were not in the mood for half-measures, and the clause was rendered mandatory. In this matter our countrymen are simply bringing themselves into line with the methods adopted by most civilised countries. During the past thirty or forty years, for instance, the medical inspection of schools has become part and parcel of the administration of State education in Austria, Sweden, the Argentine, Hungary, Norway, Switzerland, Servia, France, Japan, and Roumania. Even in Russia, that country of backward administration, the system has for some time past been applied to her secondary schools. In other countries inspection is local and voluntary, as, for instance, in Belgium, Germany, and the United States of America. So far as similar partial action is concerned, the necessity for some step of the kind has been recognised in some parts of England during the last eighteen or twenty years. A more scientific knowledge of the conditions of school life and of school diseases, and of the bearing of health questions upon the regulation of education has enabled the matter to be handled in a much more satisfactory manner than would have been possible in a previous generation. That the time for dalliance with the question has gone by is fully recognised by the attitude of the Government, which has at the present moment two Bills in hand, each of them containing provisions for the mandatory medical inspection of school children. The only plan likely to give permanent satisfaction is the creation of a central authority in the shape of a medical department of the Board of Education. The body thus created would become directly responsible to the Minister of Education for the proper organisation and efficiency of local medical inspection throughout the country. In no other way is it likely that any sound system can become established. Clearly it would connote a staff of specially skilled inspectors, for the duties of the school medical officer are multifarious and many of them of a highly technical nature. He must have a practical acquaintance with disease, for instance, especially in its communicable forms; he must be more or less of a dermatologist, an ophthalmologist, an alienist, a dental surgeon, and an expert generally in the diseases of children, not to mention that he must be able to investigate the sanitary condition and the proper construction of school premises; and to be a competent consultative authority upon a host of other technical questions. In this way the State school system of the future is likely to become a great factor in the prevention of disease, infectious and non-infectious, and most assuredly will deeply influence the future of the race. By looking after the feeding of school children, and by nipping many disorders and defects in the bud, medical inspection would be able to keep a host of citizens from swelling the vast sum total of our Poor-law wreckage. Compulsory medical school inspection, in short, belongs to that class of legislation which is penny foolish and pound-wise. It spends money in looking after the bodily welfare of the children of the people in their tender years with the view of keeping them in later life clear of the workhouse where they would have to be maintained at a vastly greater cost to the community. The desirability of medical inspection, indeed, rests on economic grounds not less obvious than those dictated by common-sense and humanity. Now that public opinion is ripe for the legislation which cannot long be delayed, it is a fitting moment for a great and well-informed international discussion to take place. Such an opportunity is forthcoming in the International Conference on School Hygiene to be held in London from August 4th to 10th, under the distinguished presidency of Sir Lauder Brunton. It is well that at this precise juncture we should obtain an authoritative account of the views and experiences of other countries on this most important social question.

CURRENT TOPICS.

Tuberculosis in London.

An important and significant meeting was held in Paddington the other day with regard to the administrative measures against tuberculosis which are considered advisable and practicable in London. The meeting was in effect a conference of representatives of all the Metropolitan boroughs, and comprised no less than seventy delegates who exhibited a remarkable degree of unanimity. The first resolution was one recommending the compulsory notification of consumption, and this was only one that met with any opposition. The general opinion of representatives of boroughs in which voluntary notification already prevails seemed to be that it had been a failure, and after discussion the resolution in favour of compulsion was passed by 47 votes to 8. The delegates perhaps hardly realised all that is involved in the resolution, for if voluntary notification has been unpopular it stands to reason that compulsory notification will be more so, and if the measure is to justify its existence it must be supported with its logical corollaries—isolation and sanatorium treatment. Considering the present state of public feeling with regard to the infectivity of consumption it is not a matter for surprise that workers who live by their own exertions should shrink from the knowledge that they are suffering from the disease coming to the ears of their employers and fellow-workers. The next resolution which was passed unanimously urged that the Local Government Board should make the regulations under the Dairies, Cowsheds, and Milkshops' Order 1885, and its amendments, compulsory on local authorities, as also that Section 69 of the Public Health (London) Act should be extended to pulmonary tuberculosis so far as it relates to the milk of cows and the sale and storage of milk. With those proposals we are heartily in agreement, but they come rather curiously on the heels of the resolution of the new London County Council to withdraw from the consideration of Parliament the milk claims that had been inserted in its new General Powers Bill. Finally it was resolved that the Metropolitan Asylums Board should be made a sanatorium authority for London—a very large and complicated question. The meeting decided to ask the President of the Local Government Board to receive a deputation, and we shall be much interested to see if the Board has altered its well-known views on these highly important questions.

The Queen's Nurses.

The issue of an appeal by Queen Alexandra's Committee reminds the world of the excellent work done by the Queen's nurses. It is hardly necessary to recall the fact that the late Queen Victoria devoted to the maintenance of nurses for the poor the interest on the sum of £70,000 subscribed by the women of the United Kingdom in honour of the Jubilee. The aim of the Queen's Institute is to supply town and country districts requiring the services of trained and competent nurses to visit and minister to the sick poor in their own homes. The value of such a movement is obvious, and it is remarkable that the Committee have been enabled to achieve so much upon the comparatively small yearly income of £8,000, of which £2,100 is from her late Majesty's endowment. A sum of £10,000 is now asked for yearly by Adeline Duchess of Bedford, who has succeeded the late Countess Cadogan as President of Queen Alexandra's Committee.

Identification by Palate.

The infinite variations of individuals from standard race peculiarities of structure have been made the basis of various systems of identification. It has remained for Dr. Paul Pragen, an Austrian Army surgeon, to point to the measurements of the human palate for that purpose. He maintains that a system founded on that basis is more efficacious than the one dependent on finger prints. He states that among the thousands of casts he has taken of the arch of the human mouth, he has failed to find any two resembling each other. Though the teeth alter greatly from time to time at various periods of life, he maintains that the markings of the palate remain unchanged throughout. The individuality of the palate, in short, is more marked and permanent than that of any other part of the human body. These observations possess a considerable scientific interest, and it is obvious that, if capable of wide application in criminal anthropology, they may prove of much practical value to the community.

The Teaching of Physiology.

WE have great pleasure in publishing in our correspondence columns a letter from Dr. D. T. Barry, Demonstrator of Physiology in Queen's College, Cork, on the teaching of physiology to medical students. This is a subject on which opinions are greatly divided at the present moment. There are not wanting those who maintain that physiology is as yet in so nascent a stage that its conclusions are of little value for the purpose of medical instruction. One well-known physician at least has not hesitated publicly to proclaim this view in print quite recently. On the other hand, there are those who wish students to delve still more deeply than they do at present into the teachings of pure physiology, holding that the present knowledge they gain is a poor equipment for scientific medical practice in after life. The overcrowded curriculum, however, may want improving; it certainly cannot stand any further loading. No practical medical educationalist, we venture to think, would propose any further addition to the student's programme, however much he might desire to see substitution and transposition brought about. The teaching of physiology is, however, a question so practical and so vitally important that we should be glad to hear what our readers' opinions on the subject are.

An Anti-Vivisectionist "Expert."

THE evidence given by Dr. Arabella Kenealy before the Royal Commission on Vivisection may, we presume, be regarded as typical of the opinions of a section at least of the anti-vivisectionist party, as otherwise she would hardly have been chosen to give evidence. This lady, who retired from practice some seven or eight years ago and has devoted herself since to what she calls "literature," has original ideas both on pathology and on treatment. "In all diseases," she says, "Nature selected the organ that should throw out the poison. In typhoid fever it was the glands of the small intestine. . . . In diphtheria Nature has selected the tonsils as the best route of eliminating the disease. By giving antitoxin one might relieve the tonsils, but one threw the poison back into the blood, so that it causes paralysis; it causes albuminuria, it causes convulsions and sudden death, rashes, and inflammation of joints. *I would make the use of the serum a penal offence.*" This is a fair example of the extravagant nonsense with which the witness regaled the Commission for many hours. It is perhaps as well that Miss Kenealy has retired from practice if she allowed the treatment of her patients to be guided by her own dictum that "disease is a natural operation of Nature, and when we attempt to thwart the operations of Nature I think we are trying to put back evolution."

Straw and Strawberries.

Now that the strawberry season is in full swing it may be well to give a word of caution to purchasers. The main thing is to choose perfectly fresh and firm fruit. Mouldy fruit is not only undesirable in itself, but in many cases it points to a special risk of infection. Most folk know that straw, placed beneath the young fruit, enables it to ripen more readily, and protects it from the depredations of various insects. So long as good straw is used, the advantage is very much in favour of the ultimate consumer. Some growers, however, replace clean straw by unclean manure. The result is that the fruit soon turns mouldy and the berries are liable to be infected with all kinds of unwholesome bacteria. The moral is, to avoid strawberries that are off colour or present a moist or mouldy surface. Fine fresh strong fruit has a look of its own, and may be consumed with a fair amount of confidence, that is to say, if we accept the doctrine of an unavoidable margin of risk. If there be any suspicion about the fruit it may be washed, or, better still, rejected altogether. Fortunately, the process of jam making involves the destruction of harmful germs.

A Royal Commission on Cancer.

THE announcement made by the Prime Minister the other day that he had in mind the question of appointing a Royal Commission on Cancer naturally marks an epoch in the history of medical science, for though other diseases have been the subjects of Royal Commissions there has always been a prospect of more or less immediate remedial benefit. With regard to cancer this cannot be expected, but on the other hand the educative value of such a Commission would be enormous. It would, or should, show the immense difficulties of the problem, and the Commissioners should certainly recommend a permanent scientific bureau adequately endowed for the systematic, continuous, and organised study of the disease. Money thus spent would be invested to the greatest advantage and would be infinitely better expended than in the pursuit of some petty party question which has existence only in the imaginations of heated politicians. Even if the Royal Commission did nothing more than inquire into the effect of cancer "cures," and the claims of irregular practitioners to treat the disease, much good might be done, especially if followed by legislation prohibiting this cruel and nefarious traffic. We have reason to believe that the Cape Parliamentary inquiry into Mrs. Van Niekerk's petition to practice cancer-curing in Cape Colony, which was described in the MEDICAL PRESS AND CIRCULAR at the time, has had a most beneficial effect, and we should warmly welcome a Royal Commission on Cancer, if only as an instalment of the Royal Commission on Quackery, which we have consistently advocated for so long. We hope Sir Henry Campbell-Bannerman will allow nothing to stand in the way of its appointment.

Administration of Anæsthetics.

A considerable amount of public attention has recently been drawn in the lay press to the administration of anæsthetics in the hospitals by unqualified men. As a matter of fact, the administrator is almost always a qualified resident, but now and then the duty is discharged by a senior student. So far as can be seen, there is no particular risk involved if the student be under supervision and is grounded in the principles of the work. The newspapers are making much of the dictum of a well-known anæsthetist to the effect that the danger is with the administrator. As a matter of fact the majority of deaths under anæsthesia take place under the hands of skilful professional anæsthetists. The plain facts of the matter appear to be that there is a certain irreducible minimum of fatal cases and that some drugs are safer than others. Under these circumstances it seems a thousand pities to attempt to prevent students from acquiring an art that they will be certain to need in many emergencies in later professional life. If it can be shown that more deaths occur under unqualified than qualified administrators at the hospitals, there is good ground for reform. On the surface it is not easy to understand why the mere acquisition of a degree or a diploma should increase the capabilities of an anæsthetist. A matter that deserves careful attention is the quality of the drug used. In some cases it is rumoured that cheap and inferior stuff is supplied to certain hospital authorities. At any rate, coroners would do well to inquire carefully into this point in dealing with cases of fatal anæsthesia.

Dugong Oil as Medicine.

The value of readily-assimilated fats and oils in many wasting diseases has long been recognised. Of late attention has been called to the dugong as the source of a medicinal oil, especially in tubercular disease. Thirty or forty years ago Dr. Hobbs, of Brisbane, pointed out the value of dugong oil in consumption, and made the further practical observation that patients could take it in a readily-assimilable form by eating the cured flesh of the animal. Fortunately dugong bacon is famed amongst epicures for its delicacy and toothsomeness, and it possesses, moreover, the sovereign quality of digestibility. As dugong fishing is chiefly a Queensland industry, an excellent opportunity here presents itself of providing our consumptives at home with an excellent remedy, and at the same time of encouraging a colonial trade. We hope to see the dugong oil and other preparations subjected to a thorough trial at our great consumption hospitals and sanatoriums.

The Queen has sent a present of boxes of chocolates to the Chelsea Hospital for Women.

PERSONAL.

We learn that Dr. Theodore Williams has been elected Honorary Fellow of Pembroke College, Oxford.

The Isle of Wight Rural District Council have appointed Dr. J. A. Gibson as medical officer for the rural district of the Isle of Wight, to fill the vacancy caused by the death of Dr. Joseph Groves, who held the appointment for a quarter of a century.

Mr. H. Rider Haggard, J.P. will distribute the prizes in the Governor's Hall, at St. Thomas's Hospital, on June 26th, at 3 p.m.

Dr. Evan Thomas and Dr. John L. Davies have been made Justices of Peace for the County of Monmouth.

Colonel Douglas Duncan has been reappointed chairman, and Professor David Finlay, vice-chairman of the St. Andrew's Ambulance Association.

Dr. R. Welsh Brainthwaite, Inspector under the Inebriates Act, will give the Norman Kerr Memorial Lecture at the Society for the Study of Inebriety, on Tuesday, October 8th.

Dr. Richard Harding, of New Radnor, has been placed on the County Commission of Peace for Radnorshire.

Sir Patrick Manson, K.C.M.G., will deliver the opening address at the first meeting of the Society of Tropical Medicine and Hygiene at 20 Hanover Square, W., on June 26th, at 8.30 p.m.

Mr. C. B. Keetley, F.R.C.S., as Cavendish Lecturer, attracted a large audience on Friday last at the annual function of the West London Medico-Chirurgical Society. An abstract of the lecture will be found in another column.

Professor Schueller, known for his investigations into cancer, has died in Berlin in consequence of infection whilst making experiments with a sort of serum.

At the Bedford County Hospital on June 20th, Mr. C. B. Lockwood, surgeon at St. Bartholomew's Hospital, gave an address entitled, "Some Remarks on Clinical Pathology in its Relation to Diagnosis and Treatment."

The last of the series of post-graduate lectures arranged for the summer session in connection with the Faculty of Medicine at the Birmingham University was delivered on June 20th, by Dr. John Robertson (Birmingham Medical Officer of Health).

It is understood that Dr. Dyer, Medical Officer of Dartmoor Prison, will succeed Dr. George Beamish at Wandsworth Prison. Dr. Beamish is retiring shortly.

The Right Hon. Sir Walter Foster, M.D., is announced to take the chair on Friday next at a public meeting of "The Association for the Prevention of Premature Burial."

At the meeting of the Board of Management of the Salford Royal Hospital on June 20th, the following appointments were made:—Resident Surgical Officer, George E. Seldon, M.D. (Toronto), M.R.C.S. (Eng.), L.R.C.P. (Lond.); House Physician, G. A. Adshead, M.B., Ch.B. (Edin.); House Surgeon, W. S. Moore, M.B., Ch.B. (Glas.).

The new Government lymph laboratories at Hendon costing upwards of £20,000, were on Saturday formally taken over by the Local Government Board medical staff. This is the only Government lymph-producing station in the country.

A Clinical Lecture
ON
DISORDERS OF MICTURITION IN WOMEN (a).

By PETER HORROCKS, M.D.Lond., F.R.C.P.,

Senior Obstetric Physician, Guy's Hospital, Lecturer on Obstetrics and Diseases of Women, Guy's Hospital Medical School, &c.

LECTURE II.

II.—FREQUENT MICTURITION.

This is a very common complaint in women. Sometimes you will find that the patient is always wanting to pass water, and she only passes a few drops at a time, after which she is scarcely at all relieved of the desire. At other times it is not so much the desire to pass it as the fact that she cannot hold it for long. You will be able to differentiate between the two classes of case by careful cross-examination. Again, it may be that she is passing a great deal too much urine, and so, relative to the quantity, it is not too often. Perhaps one of the commonest causes is a so-called *irritable bladder*. It is not always possible to discover the cause of the irritability, but if you can find a cause, it is half the battle in treatment. *Irritating urine*, caused by an excess of acidity, uric acid, urates, oxalates, and phosphates may be the cause. *Cystitis*, no matter how produced, is a common condition found, and may be acute or chronic. A careful analysis of the urine is required. *Gravel* is only excess of the solid ingredients of urine deposited in the bladder, and, passing out no longer dissolved in the urine but precipitated. *Overdistention* is often followed, for a time, at all events, by an inability to hold the urine for long. *Inflammation* round about the bladder, as in pelvic peritonitis, general peritonitis, perimetritis, parametritis, metritis, and vaginitis may produce it.

Urethritis is a prolific cause of painful and often of frequent micturition. During *pregnancy*, especially towards the latter months, it is often impossible to hold the urine long. In *diabetes*, both saccharine and insipid, micturition is frequent, because there is such a lot of urine secreted in the 24 hours. Excessive drinking of fluids acts in the same way, and when there is alcohol in the drink it aggravates it. Occasionally you will find it is due to a very *small bladder*—small congenitally, or following prolonged cystitis or injury to the bladder with sloughing. I have seen two or three cases where the lining of the bladder has been so injured during a neglected second stage of labour that it has sloughed, peeled off, and come out through the urethra. In one of these cases which was under my observation, the bladder subsequently shrank in size so much that it could not retain more than two ounces of urine, so that the lady had to pass it every half hour.

Bright's disease is sometimes indicated by frequent micturition, though in the majority of cases of nephritis it is not present. *Pyelitis* and *pyonephrosis* may cause it. *Injuries* to the bladder, as, for example, parturition, operations, explorations of bladder by dilators, cystoscopes, etc., may be followed by frequent micturition. *Coitus*, especially when excessive, acts in the same way, as does also riding on a saddle, as in *cycling*, especially when the peak is too prominent.

Pessaries which fit badly, or which are left in too long, will cause it.

Prolapse of the anterior vaginal wall with the bladder *(cystocele)* is sometimes the only cause to be discovered.

Displacements of the uterus seldom give rise to it, though you may find the cervix in retroversion and retroflexion apparently causing some irritation of the bladder. Remember that displacements are often compound; for example, you may find prolapse and cystocele, as well as the backward displacements. Pathological *anteversion* may cause it, but *anteflexion*, even when extreme, is mostly congenital, and is not a cause.

Urethral caruncle, *prolapse of the urethral mucous membrane*, *vulvitis*, *thread worms*, *irritation from dirt*, *smegma*, *etc.*, may all cause frequent micturition.

In some cases you will find the urethra apparently very thick, and this is usually due to chronic urethritis and *periurethritis*, mostly of gonorrhœal origin. *Calculus* in the bladder is a cause, but is seldom met with in women. Occasionally a small one gets stuck in the urethra, and becomes buried in the mucous membrane. If detected it can be removed, but if undetected, it may eventually either escape in the urine, or set up a small abscess, or become encysted. Careful examination along the urethra ought to enable you to discover such a condition. *Foreign bodies* in the vagina, urethra, or bladder will cause it. It is met with also, though but rarely, in *tumours*, such as fibroids, ovarious cancers, hydatids. In *extra-uterine fœtation* it is occasionally complained of, though not so often as in ordinary pregnancy.

Finally certain *nerve conditions*, spinal cord diseases, and brain affections will cause it.

TREATMENT.

Remove the cause if possible. Careful *dieting* to lessen the amount of any ingredient of the urine which appears to be in excess. Too much water, tea, coffee, mineral waters, alcoholic liquors must be remedied by taking less. Too much nitrogenous food is often the cause of uric acid troubles. A complete *change of environment* is often most beneficial, because there is not merely a change of air and scenery, but because there is rational exercise in sufficient amount, and a plain, wholesome diet. Hence the good effect of the various *hydros*, *spas*, etc., at home and abroad.

Drugs.—The most popular drug at the present time is *urotropine*. It is given in 10 grain doses in Mist. Acidi Co. ℥j. (Guy's), three times a day, and certainly it is a most useful drug in properly selected cases. My own experience has been that it acts best, speaking broadly, in cases where the urine is alkaline. It often fails to give relief where the urine is acid. One always gives it in cystitis, and it does good as a rule. But it may fail to do good, and in that case you can try one or other of the older remedies, such as buchu, uva ursi, copaiba, sandalwood oil (in capsules of 10 to 20 minims t.d.s.), or the alkalies. Benzoic acid is useful, and salol gr. x. t.d.s. have been recommended. Washing out the bladder is required to cure most cases of chronic cystitis.

(a) Two Clinical Lectures delivered at Guy's Hospital, October, 1906, and January, 1907.

Thompson's fluid, consisting of biborate of soda (borax) ʒj., glycerine ℥jj., and water ʒjj., is a good solution to use once or twice a day.

Two ounces of nitrate of silver solution (1 in 1,000, or even 1 in 500) may also be used.

A 2 per cent. solution of acidi borici; Formalin lotion (1 in 3,000).

Hydrarg perchloride (1 in 10,000).

Nitric acid (2 drops to an ounce).

Sulph quinine, gr. j., ad. ʒj.

Salicylic acid, 1 in 2,000.

Creolin, ½ per cent.

Resorcin, 1 in 750.

Iodoform Emulsion (℈jj. (scruples) ad. ℥j.).

Argyrol (30 per cent. of silver with proteid of wheat). One ounce of a 20 per cent. solution being left in the bladder.

Morphia, gr. ½ in bladder.

The above are some of the substances recommended in the treatment of chronic cystitis.

Hot hip baths and hot vaginal douches often give relief to pain. Sometimes it is a good plan to keep the bladder empty by inserting a self-retaining catheter, to which is attached a short piece of india-rubber tubing, which lies in a small dish between the thighs.

If it be necessary to examine the interior of the bladder, this can be done with a cystoscope, or the urethra can be dilated sufficiently to pass in the finger in order to make a digital examination. It is necessary to dilate with Hegars or some other form of dilator up to a diameter of from 16 to 18 millimetres, according to the size of the operator's finger. After dilatation, it is possible to use a larger cystoscope, and if need be to obtain urine from one or other of the ureters for examination, and to apply treatment to any part requiring it. The patient is apt to have incontinence of urine for some time after such an exploration. The artificial production of a vesico-vaginal fistula, by vaginal cystotomy, may be done in rare cases, for exploration, or treatment, or drainage. Suprapubic cystotomy is seldom performed in women.

In pregnancy posture often relieves the patient. The prone or semi-prone position is the best, but merely lying in a horizontal position is often sufficient, with the the feet raised or not. Any injuries caused by riding on a saddle (horse, cycle, etc.) must be remedied as much as possible. Special saddles are made with no peak or very little. Ladies complain, however, that they cannot ride so well unless there is some peak on the saddle. Still, when damage is done it should be altered, and in some cases complete rest from riding is required. Similarly, it may be necessary to remove or to alter a pessary. Tumours must be removed where possible, and inflammatory conditions in the neighbourhood of the bladder or urethra must be treated. Diabetes and Bright's disease require the treatment due to each, apart from the symptom of frequent micturition. After operations and parturition the complaint does not usually last long, time being all that is required for the parts to recover themselves. In a few cases, however, it persists a long time, and may even become permanent.

Correct uterine displacements and, if need be, fit the patient with a suitable pessary. Remove or cauterize urethral caruncles, and prolapse of urethral mucous membrane.

Urethritis frequently requires treatment by means of a solution of nitrate of silver (10 grains to the ounce), applied by means of a Playfair's probe thinly wrapped with cotton wool. It should be inserted with great care, as it is rather painful, but it is a most efficacious method of treatment. It should be done two or three times a week at first, and less frequently afterwards.

Tubercle of the urinary passages is not common. It is found more often in children and young people than later in life. There may be painful as well as frequent micturition, and sometimes a few drops of blood follow the urine. The tubercle bacilli may be found, and the patient may react to tuberculin. The opsonic treatment seems to afford a better hope of cure than older-fashioned methods.

III.—PAINFUL MICTURITION.

This often accompanies frequent micturition. Sometimes, however, the patient will hold her water longer than usual to avoid the pain set up by the act. The commonest cause is *urethritis*, which is usually of gonorrhœal origin. When acute, the pain is mostly described as scalding. This smarting, scalding sensation, caused by the urine flowing over the inflamed urethral mucous membrane, lasts from a few days to a few weeks, or even months, according to the severity of the case, the sensitiveness of the patient, and the treatment. The pain gradually lessens and finally disappears, long before the urethritis is cured. On pressing the urethra from the sphincter vesicæ to the meatus, a drop of pus is squeezed out. This is considered by some quite pathognomic of gonorrhœa. In *acute cystitis* there is often painful micturition, but it passes off as a rule when the cystitis has become chronic. It is a curious fact that gonorrhœa is not usually a cause of cystitis in women. It produces vulvitis, vaginitis, and urethritis almost invariably, but it seldom spreads into the bladder.

Urethral caruncle. The ordinary one, so frequently met with is very red in colour, much brighter than the pale rose colour of the vaginal mucous membrane. It is usually small, not bigger than a pea, but more pyriform in shape. It is exquisitively sensitive. The pale variety of caruncle is as a rule not at all sensitive, does not cause painful micturition, and is mostly a product of gonorrhœal inflammation. *Irritating urine*, containing pus, blood, urates, oxalates, phosphates, sugar, or too much acidity, may cause pain.

Inflammations round the bladder and urethra (parametritis, perimetritis, and periurethritis), are causes.

Lupus minimus nearly always causes painful micturition, and is often met with in women after the climacteric. You find tiny, painful red spots, mostly with small ulcerated surfaces, which are very tender. Their favourite site is along the line of the hymen or carunculæ myrtiformes up to the meatus urinarius. Hence the urine is apt to flow over them and cause pain.

Growth in the bladder (cancer, villous, polypi-tubercle) may or may not cause pain. In some cases they cause pain owing to the formation of clots, which have to be expelled.

Injuries to meatus urinarius, urethra, or bladder, caused by excessive riding on horseback, cycling, coitus, parturition, accident, operations, kicks, blows, stabs, insertion of foreign bodies into urethra and bladder or vagina, may cause or lead to painful micturition.

Fissures or *ulcers* or *spasm* about the neck of the bladder are rare causes of this complaint.

Eczema vulvæ due to pruritus, diabetes, or other cause, may give rise to pain if the urine flows over any part of it, which will occur in some cases when the parts are greatly swollen.

Foreign bodies are much more frequently found in the urethra and bladder of women than in men. Hairpins, pencils, pens, etc. If within reach it is easy to diagnose the case; but where the substance has passed into the cavity of the bladder, it is not always easy to make it out, particularly as the girl (she is usually young) is too much ashamed to tell what has happened. *Calculi* may cause pain, but it is generally the gravel that accompanies it that is responsible. In rare cases, however, a calculus sticks fast in the urethral canal, and so causes pain. It is easily felt, but it may become embedded and encysted, and cause suppuration, which may open into the urethral canal, or it may open (or be opened) into the vagina. *Cancer* about the meatus, vestibule, vulva, urethra, may have a sore surface which causes great pain when the urine flows over it. In some cases no cause, apparently, can be discovered, and one is obliged to resort to the term *hyperæsthesia*.

TREATMENT.

Acute urethritis and acute cystitis should be treated by rendering the urine as non-irritating as possible, namely, by a careful diet of plain food without any alcohol, the administration of alkalies, a great favourite being the following mixture: Pot. citratis ʒss., Tinct. Hyoscy. ʒss., Inf. Buchu ad. ℥j t.d.s. You must insist on a fresh solution of the buchu to obtain a good result. It is not at all a nice medicine to take, but it is very efficacious. Hot applications over the bladder and vulva give relief, and in some cases, especially if carefully done, a hot stream of water made to impinge on the urethra per vaginam, gives ease. Later, when the acute stage is over, you can apply local applications along the urethral canal, of which a solution of nitrate of silver, gr. x. ad. ℥j., is the best.

The treatment of chronic cystitis has been already described. The ordinary bright-red painful urethral caruncle should be burnt off by means of the thermo-cautery. It is much the best plan to give an anæsthetic in order to save the patient pain, and to enable the operator to burn out the root. It is possible to remove them under cocaine, but you will find this method less satisfactory. A few drops of a 20 per cent. solution should be applied or, better still, two drops of a 5 per cent. solution injected with a needle into the root. Never snip them off with scissors, as they are apt to bleed a long time. Of course, if you are prepared to burn the root after snipping off, well and good. Also never try to tear them off by twisting, or to cure them by a ligature; in both these ways you leave roots from which another caruncle may grow. If, after burning a caruncle out, recurrence should take place, suspect malignancy. It may not be malignant, but it should now be removed with the knife or scissors, the base being cauterized, and the part removed carefully examined microscopically. The pale varieties of caruncle can often be cured by applying lotio nigra, or $AgNO_3$ solution (gr. x. ad. ℥j.). They may be snipped off, or cauterized, if need be.

Irritating urine should be treated by careful dieting, according to the ingredients which are in excess. Frequently it is necessary to lessen the amount of nitrogenous food, and to omit alcohol absolutely. The administration of alkalies, acids, antiseptics, urotropine, must be left to your discretion. You may be called upon to treat kidney disease, or to wash out the bladder.

Inflammation must be treated as has been already described.

Lupus minimus is by no means easy to cure. As a rule sedative lotions give most relief, such as lead and opium lotion; hot boracic acid lotion and the like. But lotio nigra, or touching the spots with the cautery, are more likely to cure them. Growths in the bladder must be removed when possible. Rendering the urine alkaline relieves the pain in many cases.

Injuries must be repaired as far as possible, and any source of injury constantly taking place, such as excessive riding and cycling, must be lessened. Mention has been made of the shape of the saddle, the peak being sometimes too pointed, thus pressing unduly on the lower end of the urethra. Coitus may be excessive or may cause painful micturition through some peculiarity of relative position, even when not excessive, both of which may be remedied if you give suitable advice. Other injuries must be treated on ordinary lines. Tears, cuts, lacerations, may be sewn up. Fissures and ulcers and spasm about the neck of the bladder may be treated by local application of caustics, but dilatation of the urethral canal is, as a rule, necessary. In obstinate cases it may be necessary to do cystotomy per-vaginam and so get at the seat of trouble. Foreign bodies and calculi must be removed. Cancer must be removed if possible. In cases of hyperæsthesia the application of sedatives locally, and alkalies and bromides and the like internally, give the best results. Eczema must be treated according to the cause.

IV.—INCONTINENCE OF URINE.

Sometimes, when the bladder gets over-distended, urine is either constantly or intermittently dribbling away. This is called false incontinence, and is easily diagnosed by discovering the distended bladder, and easily cured by passing a catheter until the normal tone has been regained.

True incontinence is where the urine dribbles away as fast as it flows into the bladder, as, for example, where there is a large vesico-vaginal fistula, or where it dribbles more or less intermittently in spite of the patients efforts at control, and without any distention from retention. The commonest cause of true incontinence is some form of fistula. The commonest is a vesico-vaginal fistula, and is most frequently caused by damage done through the pressure of the child during a prolonged second stage of labour. Given a disproportion of parts caused by a large child, or a small pelvis, or by both, it is obvious that the pelvic viscera will be damaged, particularly if the condition is not recognised early enough to afford relief before the damage is done. As a rule, the incontinence does not begin directly after the child is born. But, more or less, of the trigone of the bladder, with the corresponding portion of the anterior vaginal wall, has its nutrition interfered with to such an extent, and for so long a time, that it sloughs out some days after labour, and leaves a hole between the vagina and the bladder, through which the urine flows as fast as it escapes from the ureters. The patient is constantly wet. If she is in bed everything under her is wet. If she is walking about her vulva and thighs and linen are constantly soaked in urine, which decomposes and gives rise to a strong ammoniacal odour. Deposit of salts from evaporation results, and the irritation and friction of the thighs lead to an eczematous condition of the skin.

Fistulæ may result from the ulcerating progress of cancer of the cervix uteri, vaginal walls, urethra, or, in rare cases, the body of the uterus. They may follow operations on the same parts, and from other injuries, accidental or wilful, and they may be congenital. Sometimes there is true incontinence with hypospadias. In addition to the ordinary and most common fistula, namely, that between the bladder and vagina (vesico-vaginal), you meet with urethro-vaginal, vesico-utero-vaginal, vesico-uterine, and uretero-vaginal fistulæ. Cystitis is sometimes a cause of incontinence. According to some authorities, hysteria is never a cause, and if there is incontinence of urine in a woman with convulsions, it is said this proves they are not hysterical. In an epileptic fit the urine is not infrequently voided involuntarily. When the fit is not epileptic, but simulates hysteria, the mere fact of voidance of urine during an attack brings the case, according to some, into the category of Hystero-epilepsy. I cannot say that I altogether agree with this, for I have seen cases which appeared to me to be genuinely hysterical, and yet where the patient passed urine and wetted herself during the attack, and hence I feel inclined to put hysteria down as an occasional cause, although I am free to admit it is open to doubt. Incontinence is met with also in certain cases where the bladder is displaced by tumours, especially when the neck of the bladder (sphincter vesicæ) is disturbed.

Again, there is an involuntary dribbling of urine in some women whenever they do anything which increases the intra-abdominal pressure more or less, as, for example, during coughing, laughing, sneezing, retching, defœcation, etc., and, *a fortiori*, during heavy work, such as washing, laundry work, lifting patients or other heavy weights, scrubbing floors, etc., or during play which involves strain, such as golf, tennis, hunting, etc. This kind of dribbling is very common in the latter months of pregnancy in some women. You will frequently find it associated with more or less prolapse of the bladder and anterior vaginal wall, especially when the cystocele involves the neck of the bladder and the first portion of the urethra. Incontinence sometimes follows dilatation of the urethra by dilators, cystoscope, etc.

Nocturnal incontinence is met with chiefly in children. Every child requires training, but it takes a much longer time to train some children not to wet the bed during sleep than others. Where this bad habit remains, it is in some cases apparently no more than a bad habit, in others it is hereditary, and in some instances it is distinctly the result of a bad dream, the urine being voided at that point of the dream where the individual is in terror. Most of these cases dating from childhood get better about or soon after puberty. If you find a case where good habits were instilled in childhood, and where nocturnal incontinence has begun subsequently, as, for example, after puberty, always suspect epilepsy. It has been my privilege to see many cases of nocturnal incontinence due to unsuspected epilepsy, either the Petit or Haut Mal. In one case the mother told me her daughter was always very lethargic, and had a headache the morning after there had been nocturnal incontinence. In another case a little blood was found on the pillow, and on examining the tongue I found it had been bitten during the epileptic attack. In another the pillow was always wet with salivary foam, caused by the fit. In any case, therefore, of nocturnal incontinence coming on, say, after puberty, or even before, when there has been some years of a normal condition, it is as well to make minute inquiries to throw light on the possibility of epilepsy as the cause, and to get the patient to sleep with her mother, sister, or lady relative or friend, or a nurse, in order to establish the diagnosis. This is easy if it be a case of Haut Mal, but difficult in the Petit Mal instances. The diagnosis of the latter can be fairly established when the patient only occasionally passes urine in her sleep, and when on each of those occasions she wakes up with a headache and feels lethargic.

TREATMENT OF INCONTINENCE.

Marion Sims first became famous by his success in repairing vesico-vaginal fistulæ, and since his time the evolution of asepsis has made possible the repair of fistulæ which used to be considered hopeless. Some are quite easy to do, and some very difficult. It is not always possible to cure a case by one operation, it may be necessary to do it in two or more steps. The edges of the opening are made raw, and are then carefully brought together by sutures, and the bladder is kept empty by means of a self-retaining catheter until the surfaces are united sufficiently to hold—that is, for three or four days at least. If catgut be used, it will not be necessary to remove the ligatures by cutting them, at any rate. If silk, or silkworm gut, be used, then, of course, they must be removed in seven to ten days. Incisions of cicatrices to loosen the parts, separation of bladder wall from vaginal wall, separation of bladder from anterior surface of the cervix uteri, may be severally required to permit the raw edges to be brought together.

In some cases transplantation of mucous membrane has been successful. Colpocleisis, or closing the vagina, is condemned by some authorities. I have no experience of it, but I think it is worth trying in bad cases. When it is impossible to cure the case the question of wearing a urinal arises. I have never come across a satisfactory urinal. They are expensive and inconvenient, and troublesome to keep clean, and so I generally recommend such patients to wear a thick pad of some highly absorbent and cheap material, throwing it away as often as need be. The thighs and vulva are to be protected by smearing over them some unguent like vaseline.

Incontinence due to bruising and injuries must be treated by rest, hot application, and drainage of the bladder, and, if need be, temporary cystotomy. Cystitis must be treated as already described. Hysteria must be treated by studied neglect. Cystocele requires a suitable support, according to its severity. A small ring pessary, a Galabin's anteversion cradle pessary, or a red rubber cup and stem (Napier's) pessary, are, I think, the three best. Colporraphy is seldom required. Incontinence following dilatation of the urethra usually gets well itself after a few days. If not, assistance may be given by the application of astringents.

Nocturnal incontinence is treated by careful training, giving little fluid at night before going to bed, giving large doses of belladonna, in some instances beginning with ten drops of the tincture bellad. in a little syrup and water, it has been found necessary to gradually increase the dose up to as much as sixty drops or more of the tincture every night before attaining the desired result. Its physiological effects must be watched carefully. Sedatives, such as opiates and chloral, are sometimes useful. The injection of half a grain of morphia, in solution, into the bladder has been recommended, as has also a solution of nitrate of silver, 10 grains to the ounce. It must always be remembered that children tend to grow out of the habit as they obtain and pass puberty. When due to epilepsy, of course the cause is of far greater import than the symptom. The epilepsy must be treated. The dribbling from over-distention is treated by catheterism, a self-retaining catheter being worn for a time if requisite. Sedatives and injections into the bladder are sometimes helpful, but a little time and patience is all that is usually necessary so long as the cause of the retention can be removed. The dribbling in pregnancy is best treated by posture, the prone or semi-prone being the best. That which occurs during coughing and other strains is treated by curing the cough, diminishing the strain if possible, giving astringent vaginal injections, or fitting a suitable pessary.

HÆMATURIA.

Always make sure that the blood does come from the urinary passage. As you know, menses often get into the urine, and sometimes blood from other parts, such as from the cervix uteri, or from piles, may simulate hæmaturia. Whenever there is any doubt, it is well to obtain a catheter specimen and examine it when freshly drawn. Be sure it is blood. Test for albumen, and blood, and see the corpuscles under a microscope. The blood may come from the urethra, bladder, ureter, or kidneys, and, theoretically, it may get into those urinary passages from neighbouring parts, though this is rare. Probably the most frequent cause of hæmaturia in women is congestion or inflammation of the kidneys in pregnancy, especially in primiparæ. You may get it from the same cause apart from pregnancy. Injuries to the kidneys or any part of the urinary passages, calculi, pyelitis, cancer in kidney, ureter, bladder, or urethra, cantharides and other drugs, some fevers, and the bilharzia hæmatobia, all cause hæmaturia. Tuberculous disease sometimes affects the kidneys, or ureter, or bladder, and may cause some hæmorrhage. In a few cases the hæmaturia is factitious.

The treatment of hæmaturia resolves itself into the treatment of its causes. In the common form of congestion, and perhaps inflammation, of the kidneys associated with pregnancy, and particularly in primiparæ, you have to carefully estimate the amount of albuminuria, the amount of urea, and the state of the patient. A threatening eclampsia may necessitate the premature emptying of the uterus, which will usually relieve the kidney condition. The hæmaturia in these cases is not of long duration, but subsides sooner or later into mere albuminuria. Cancer tubercle and injuries must be treated as the case requires. Bladder tumours can often be removed, either by dilatation of the urethra, vaginal or supra-pubic cystotomy, and then the use of the finger, knife, scissors, snare, or cautery,

Note.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by Leonard Williams, M.D., M.R.C.P., Physician to the French Hospital, London, Assistant Physician to the Metropolitan Hospital. Subject : "Some of the Organic Consequences of High Blood Pressure."*

ORIGINAL PAPERS.

THE VALUE OF THE WIDAL REACTION IN THE DIAGNOSIS OF TYPHOID FEVER, AS ASCERTAINED BY ITS USE ON 230 OCCASIONS (a).

By W. JAMES WILSON, B.A., M.B., D.P.H.Camb.

Riddel Demonstrator in Pathology and Bacteriology, Queen's College, Belfast.

The apology I have to offer for bringing at this late date this subject before a meeting of this Society is the fact that many clinicians here are still unconvinced that the Widal test is thoroughly reliable, and fail to recognise that apart from the isolation of the typhoid bacillus it is the most specific factor to be reckoned with in the diagnosis of enteric fever.

Before dealing with an analysis of the cases, I should like to mention some of the essentials necessary to obtain accurate results in performing the test :—

(1) The strain of bacillus employed.—A culture is required which forms a uniform emulsion in saline solution, and which is readily clumped by typhoid immune serum, but which has no tendency to form "pseudo"-clumps. A young (*i.e.*, 12-24 hours old) Agar culture should always be employed, as the bacilli then clump readily when the specific agglutinins are present, but do not form spontaneous clumps.

(2) I have found a 1 in 50 dilution of the serum and a time limit of 1 hour satisfactory.

It must be borne in mind that it is not possible in every case to say definitely that the reaction is positive or negative. In most cases a definite expression of opinion can be given; in a few, however, in which indefinite clumping and loss of motility occur, one cannot be dogmatic. In making a diagnosis in such a case, one would have to be guided by the other signs and symptoms. To make my meaning plain, I should say that in performing the Widal test we do not always get black or white effects, but occasionally grey.

ANALYSIS OF THE CASES.

Of the 230 cases, 112 gave a positive and 118 a negative reaction. Of the 112 positive reactions, 108 were definitely pronounced positive, whilst four gave indefinite clumping and were pronounced "feebly positive."

Let us first of all dispose of these four cases. One of them was eventually diagnosed gastritis, a second mild typhoid, whilst two were cases of typhus fever. On inquiry it was found that both these typhus fever cases had had typhoid fever; one of them nine years previously, the other at a later date.

The previous attack of typhoid fever probably accounts for the reaction occurring in these cases, as I have found that the blood of a healthy individual who had had typhoid fever 22 years ago still caused a feeble agglutination of the typhoid bacillus in 1 in 50 dilution of the serum. I may add that I have examined the blood of four other cases of typhus fever, and have found it give a negative reaction.

Of the 108 cases definitely pronounced positive, 105 were suffering from typhoid fever at the time, one, a case of influenza, had had typhoid fever six months previously, one had purpura, and another a disease which was not typhoid fever. In these last two cases it was not ascertained whether the patients had previously had typhoid fever.

Taking the Widal test to indicate that the patient either was suffering from or had suffered from typhoid fever, we find that this is indicated in 109 of the 112 cases giving a positive reaction; in other words, the laboratory diagnosis corresponded with the clinical course of the disease in 97.3 per cent. of the cases.

Of the 118 negative results, 108 had not, whilst 10 had typhoid fever. In other words, our results were correct in 91.5 per cent. of the cases.

REMARKS ON SOME OF THE POSITIVE CASES.

A case which shows the value of the Widal test, and its immense service in the sphere of preventive medicine, is the following :—A woman, the wife of a byreman, had an attack of what appeared to be influenza complicated with jaundice. The patient was back at her work—milking cows—three weeks after the onset of the illness. A fortnight after the woman resumed milking an outbreak of typhoid fever occurred in the Windsor district of Belfast, and it was found that nearly all the cases, some 30 in number, received milk from this particular dairy. On inspection by the Public Health Authorities it was found that the premises occupied by this woman were in a highly insanitary state. A specimen of the woman's blood sent to the laboratory for examination gave a markedly positive reaction with the typhoid bacillus. The woman was then prevented handling the milk, with the result that three weeks later the last case among customers supplied with milk from this dairy occurred. I have no doubt that the secretions and excretions of this woman contained the typhoid bacillus.

(a) Read before the Ulster Medical Society, March, 1907.

The noteworthy points in this case are: (1) That an infection with the bacillus typhosus may be present and yet the patient may not present the classic symptoms of typhoid fever; (2) That in this case the examination of the blood indicated the cause of the outbreak, and the information afforded was proved to be correct by the subsequent history of the epidemic. Epidemics which at first sight appear to support the *de novo* origin of typhoid fever may be due to the fact that the carriers of infection have not presented a typical clinical picture. Cases of catarrhal jaundice due to the typhoid bacillus have been reported in patients who had not suffered from typhoid fever (*vide Lancet*, February 23rd, 1907). Many years ago Dr. T. Houston of this school reported from Sir John Byers' wards a case of cystitis due to the typhoid bacillus, and found that the blood of the patient clumped the bacillus. No history of a previous attack of typhoid fever could be elicited.

A case, the blood of which gave a positive result, but in which the clinical course was quite unlike typhoid, subsequently developed purpuric spots, and the diagnosis of purpura was made. Here we may note that De Benedetti (Arch. de Méd. des enf., 1904) has shown that many cases of purpura simplex are due to infection with B. coli communis. Osler mentions that one may get erythema nodosum in the course of typhoid fever. This case, then, if not an instance of infection with the typhoid bacillus, may have been an infection with a closely allied organism.

REMARKS ON SOME OF THE NEGATIVE RESULTS.

It was my custom, on finding a blood give a negative reaction in a case in which the physician in charge strongly suspected typhoid fever, to try to get a catheter specimen of urine, on the chance of finding in it a Paratyphoid bacillus. This procedure brought to light a rather interesting case. A woman, æt. 22, was admitted into one of Professor Lindsay's wards with a history of malaise of over a week's duration. Her temperature was 103.5, pulse 114; she had also the flushed face, severe frontal headache, and distended abdomen characteristic of typhoid fever. Her blood gave a negative reaction. It was found that she had complete constipation for a fortnight. On the day after admission, as the result of an enema, her temperature dropped two degrees. On the following day, after a second enema, her temperature became normal, and continued normal.

The interesting feature of this case was that during the time the girl was in hospital she was excreting large numbers of B. coli communis in her urine, although she had no symptoms of kidney or bladder trouble. The spleen was palpable, and on a certain day she had a dozen typical typhoid spots on the abdomen. Her blood continued to be negative to the bacillus typhosus, and it had no agglutinative action on the colon bacillus isolated from her urine.

This was probably a case of "fæcal fever," a condition for the occurrence of which Nothnagel cites reputable authorities.

In this case bacteriological examination showed that not only toxines, but bacilli also, were absorbed from the intestine and excreted in the urine.

Two other of the negative cases are of interest as being examples of "worm fever." The general appearance of the patients suggested typhoid fever, the temperature was 102 deg. F. After a few days each of the patients passed two round worms, and after this the symptoms cleared up.

Examination of the urine in another negative case in which the medical attendant strongly suspected typhoid fever showed that it contained a pure culture of a streptococcus of the fæcalis type. Inquiry elicited the information that the illness came on after confinement. This was evidently a case of septicæmia. The patient eventually got quite well.

A case of typhoid which showed that it may be late in the disease before a reaction is given was that of a medical student. On two occasions his blood gave a negative reaction; when tried a third time, just before convalescence set in, it gave a positive result.

A short account of a case which appeared to me, and to Dr. E. H. M. Milligen (Belfast), under whose care the patient was, to be one of generalised blastomycosis, may be given here.

The patient suffered from tonsillitis, accompanied by moderate pyrexia. A swab from the throat revealed the presence of yeast cells, which grew at body temperature, and which had no tendency to form filaments such as are met with in cultures of oïdium albicans. The yeasts were found by Professor Symmers on intravenous inoculation to kill a rabbit in two days. The patients general condition may be described as one of continued fever. At times there was pain and swelling of the knee and wrist joints. A pneumonic condition of the lungs occurred in the middle of the illness, and numerous yeasts were found in the blood-stained sputum. Yeasts were also found in two catheter specimens of his urine, but these did not grow at body temperature. After a lingering illness of five months duration the patient died, but, unfortunately, we were unable to get a post-mortem examination. The opsonic power of the patient's blood tested on the yeasts isolated from the throat was double the normal.

This, so far as I know, is the first occasion on which the opsonic index of a person's blood with regard to a pathogenic yeast has been tested. I have found that in films stained by Leishman's method the yeast cells take on a greenish colour quite different from the dark violet colour of the nuclei of the cells with which otherwise they might be confounded.

NOTE.—Since reading the above paper in conjunction with Professor Symmers I have examined the blood of 20 cases of cerebro-spinal fever with reference to its action on the typhoid bacillus in dilutions of 1 in 50 and upwards. On 15 occasions the reaction was negative, on five it was positive. In an epidemic of cerebro-spinal fever the blood of some of the cases may clump the typhoid bacillus in as high dilutions as 1 in 200, and yet the clinical picture and the post-mortem findings point to cerebro-spinal fever. But the agglutinative effect of the blood of cerebro-spinal fever patients on the bacilli of the coli-typhoid group we reserve for a special communication.

Society of Apothecaries of London, June, 1907.

The following candidates passed in:—*Surgery*.—M. L. Ford (Section I.), Charing Cross Hospital; S. F. Fouracre (Section II.), Charing Cross Hospital; O. C. H. L. Moll (Section I.), Guy's Hospital. *Forensic Medicine*.—P. D. Pickles, Leeds; G. L. Walker, Leeds. *Midwifery*.—J. M. Murray, Royal Free Hospital and Durham. A. Sheppard, Guy's Hospital. The diploma of the society was granted to the following candidates, entitling them to practise Medicine, Surgery and Midwifery:—S. F. Fouracre, A. Sheppard, and G. L. Walker.

CONSERVATIVE SURGERY IN ABDOMINAL OPERATIONS:

An Abstract of the Cavendish Lecture. (a)

By C. B. KEETLEY, F.R.C.S.,

Senior Surgeon to the West London Hospital.

There are Liberals and Conservatives among surgeons as among politicians, remarked the lecturer; some, perhaps, too ready to remove parts, and others too anxious to preserve them. After referring to the desirability of not removing ovaries and tubes unnecessarily and of preferring, where it could be safely done, the enucleation of fibroids to hysterectomy, he spoke of the vermiform appendix. In February, 1888, Treves, in a now classical paper read before the Royal Medical and Chirurgical Society, described his first operation on this organ. This was what is now known as an "interval operation." A distorted appendix was straightened out and then left in the peritoneal cavity, but Treves recommended that in future appendices which had caused recurrent attacks of appendicitis, should be removed. The appendix was then and for the next sixteen years regarded as a mere vestigial organism of no value to anybody except the pathologist and the surgeon. But in 1904, Macewen threw doubts on this view, based partly on the after-history of some of his cases and partly upon observations made in a case in which a portion of the abdominal wall had been accidentally removed as well as of the cæcum, and the orifice of the appendix exposed to view. Further, Weir, by his first operation of appendicostomy, had demonstrated that the appendix could be put to a surgical use.

What inference was to be drawn? Why that when about to amputate a given appendix we should ask ourselves whether, in that particular case, it would not be better to preserve it, reverting to the original conservative operations of Treves and of Charters Symonds (who had removed fæcal concretions from the appendix, leaving the organ *in situ*), but modifying them considerably, so as to give them safety and sufficiency.

How was that to be done? The answer was, by transferring the appendix from the peritoneal cavity and embedding it in the abdominal wall, and by opening or amputating its distal end, if its lumen was anywhere narrowed by stricture or by other cause—not a mere appendicostomy in which all but the stump of the organ is cut off, but the preservation and transference of the whole or of the greater part of the appendix. The cases for this proceeding had to be carefully selected. A fair length of the proximal part of the appendix should be free from stricture, kink, ulceration, and perforation, or it should be possible to cure such defects by, *e.g.*, opening the appendix at its distal end. Various kinds of appendix, of which a list was enumerated, were unsuited for preservation, *e.g.*, the tuberculous and actinomycotic. It was important to take care of the appendicular artery. Most of the appendix was to be placed on the external oblique beneath the fat.

The lecturer then spoke of the surgical treatment of chronic constipation. He referred to Mansell Mouillin's application of ileo-sigmoidostomy to this purpose and, at considerable length, to Mr. Arbuthnot Lane's contributions to this department of Surgery. The lecturer did not think that much could be expected from ileo-sigmoidostomy as a treatment of chronic constipation. The fluid fæces must quickly find their way back from the sigmoid or from the rectum up through the whole length of the colon, which, indeed, when the lower end of the ileum was completely divided, became one long cæcum. Experience and experiment showed that this was exactly what did take place. He ridiculed the practice of referring to the cæcum as a cesspool. It was a rounded bag of living tissue, with an aperture of egress of diameter nearly equal to its own, with a lining of secreting and of absorbing epithelium, and a muscular wall. It was compressed by the muscles of the abdominal parieties, and it contained nearly always, gas rather than fæces.

With regard to excising the colon for habitual constipation, that might seem to some the practical application of Metchnikoff's theory of the influence of the bacteria of the large intestine in causing the degenerations of old age. But it was not the only way in which these bacteria could be dealt with. There was Metchnikoff's own plan of a special diet of fermented milk, there were hygienic measures, including strict sterilisation of food, and cleanliness begun in early infancy, and there was appendicostomy.

For the surgical treatment of obstinate chronic constipation, the lecturer himself practised appendicostomy. He had operated in nine cases of the kind, in every one of which the operation had answered its purpose, *i.e.*, the large intestine could be washed out through the appendicostomy with warm water, mixed in some of the cases with a proportion of the sulphates of soda and magnesia. An appendicostomy properly performed was a clean opening not giving egress to fæces, and not requiring a catheter to be kept in. Certain drawbacks were mentioned and modes of dealing with them, and a special catheter noticed. It was made by Montagu of New Bond Street, it was of rubber, and had a long tapering point beyond the eye.

(a) Delivered before the West London Medical and Chirurgical Society, June 21st, 1907.

CLINICAL RECORDS.

THREE CASES OF ACUTE PNEUMONIA.

By S. J. ROSS, M.D.,

Surgeon for Out-patients, Bedford County Hospital.

The first case is that of a youth who caught a chill after a cycle ride. The morning after the cycle ride he complained of a slight sore throat and pains in his limbs. The following evening he had a rigor, and when I saw him his temperature was 104 deg., he was breathing rapidly, and there was impaired resonance at the base of the right lung with crepitations. I ordered a Gamgee jacket to be applied, placed him on milk diet, and gave him an effervescing quinine mixture to be taken every four hours. Crisis occurred on the seventh day, and the patient made an uninterrupted recovery.

Case 2. A child, æt. 6 years, had an attack of vomiting, refused food because it hurt her to swallow, and became feverish. I saw her on the third day of her illness. She was restless, constantly putting her finger in her left ear, had a temperature of 103 deg.; respiration, 26. She had a patch of broncho pneumonia in her left lung. The same evening the left ear discharged pus, which was very thin, and yielded the diplococcus. Crisis occurred on the fifth day. The child made an uninterrupted recovery, the perforation in the left tympanic membrane rapidly healing.

Case 3. The patient was a baker by trade, æt. 75 years. I saw him on the fourth day of his illness, which commenced with a rigor. His left lung was solid, and he had consolidation of the base of the right lung. His pulse was full and regular. Never at any time during the attack was there any sign of circulatory failure. On the fourteenth day I was summoned to see him as he had suddenly collapsed. His temperature I was informed was normal, and he was bathed in perspiration. Crisis had evidently occurred. I saw him about an hour later. He was bathed in profuse prespiration, and was almost pulseless. I gave him a hypodermic injection of strychnine, and a pint of saline by the bowel, but he never rallied, and died about one hour after I saw him.

These cases appear to be of interest for the following reasons: The first two patients complained of sore throats in the initial stages of their attacks. Doubtless the offending organisms primarily attacked the tonsils. The first case shows how simple treatment is required for an uncomplicated case of acute pneumonia occurring in a robust patient. We are apt to forget that pneumonia is a specific fever which runs a definite course, and our chief duty is to watch the circulation carefully, to discover complications if such arise, and treat them energetically.

The second case is of interest on account of the pneumococcic otites which complicated the pneumonic attack. Doubtless this infection occurred from the tonsils by way of the eustachian tube. Unfortunately children do not expectorate, and therefore I could not obtain any sputum for bacteriological examination. It is noteworthy how rapidly perforations in the tympanic membranes of children heal, if the parts be kept clean. I have noticed frequently that pus from a pneumococcic infection is thin, and apparently far less offensive than pus produced by other organisms.

The third case is a warning. The patient's circulatory condition throughout the attack was always satisfactory. No stimulants were given, and when the crisis occurred circulatory failure for the first time appeared. We are apt to regard the crisis of pneumonia as an unmixed blessing, but in aged patients it may, as in this case, spell disaster. I do not think that our medical works lay sufficient stress upon this point. Therefore I think that the notes of such a case as this may help other practitioners to avoid disaster. Many similar cases must have happened in other practitioners' practices, but alas! we hear little of failures but a great deal about successes. It would be a most useful venture if you would publish a "confessional number" of your valuable paper.

OPERATING THEATRES.

ST. THOMAS'S HOSPITAL.

Case of Tuberculosis of the Occipital Lobe.—Mr. Edred Corner operated on a woman, æt. 34, who for many years had suffered from headache and sickness. She had been in several hospitals where she had been treated without success. During the last year or two her vision had become affected: she could see objects, but the field of vision was much contracted. Ophthalmoscopic examination showed optic neuritis of both eyes. Thus she presented the three classical symptoms of cerebral tumour: headache, vomiting and optic neuritis. The headache was referred to the back of the head. She presented neither motor nor sensory symptoms. Operation had been offered to her previously, but had been declined. She had been admitted to St. Thomas's Hospital at her own desire, to undergo operation. The diagnosis made was a tumour above or below the tentorium cerebelli. The right side of the occipital region of the head was, Mr. Corner pointed out, hyperæsthetic to touch and very painful on percussion. The scalp was shaved and prepared previous to the patient being brought into the operating theatre. It had been determined to explore the right occipital region of the skull in the hope of either removing the tumour or of relieving the intra-cranial pressure and ameliorating her symptoms. After a large flap had been turned down from the occipital region of the skull, the bone was trephined. The dura mater, when the disc of bone had been removed from the trephine opening, bulged. The opening was then enlarged so as to expose the lateral sinus which, Mr. Corner had already pointed out, lay between the layers of the tentorium. It was in consequence a useful guide to the operator, as the occipital lobe of the cerebrum lies above it and the cerebellum lies below it. When the opening had been sufficiently enlarged the dura mater below the sinus was incised to expose the cerebellum, which was found to be pale and compressed by the downward bulging of the tentorium. Under these circumstances it was not interfered with. It would be a great pity, Mr. Corner said, to injure the cerebellum, as it swells subsequently, and having the strong tentorium above it, would tend to compress the medulla oblongata which is below it. The dura mater above the lateral sinus was then incised freely to expose the occipital lobe. The source of this patient's trouble was now exposed to view: the brain was adherent to the upper surface of the tentorium; it was studded with tuberculous foci which varied in size from that of a millet seed to that of a small marble; the smaller of these foci were grey, the larger were yellow and consisted of caseous material. The disease was greatest on the posterior and under surface of the lobe, where the tuberculous foci were largest and most plentiful. From these areas the disease extended forwards, the foci decreasing in quantity the further forward they were present. The character and extent of the mischief forbade the practice of any radical measures, and it was necessary to be contented with drawing the flap of dura mater over the surface of the brain. It was not advisable, Mr. Corner thought, to attempt to close the incision in the dura mater in such a case because the only object which the operation could attain was to relieve the intra-cranial pressure, and this might be defeated if the dura mater was sutured. The skin flap was replaced and united with stitches of silkworm gut and the wound dressed.

Mr. Corner said that the operation relieves the headache, the sickness, and stays the optic neuritis. The patient would be much relieved. In their convalescence these patients are prone to develop a hernia cerebri, the results of their raised intra-cranial pressure. This hernia may give a great deal of trouble to those who look after the case. It can only be relieved; it cannot be cured, as it is merely a sign or symptom of the intra-cranial disease, which the operation has been powerless to eradicate. It was, he considered, of assistance in obviating the development of this hernia if at the operation the surgeon was careful to make a large aperture in the skull, because it was a clinical fact that herniæ form more easily through small openings than large ones. This can easily be accomplished by enlarging the original trephine opening by means of Hoffman's forceps; for the effective use of instrument the operator must not be too ambitious, contenting himself with removing small fragments and not attempting to wrench off larger pieces. In tearing away larger pieces of the skull dangerous accidents happen from time to time, such as one of the sinuses being torn. If a little care be exercised in separating the dura mater from the inner table, it is quite easy to remove the bone from over these sinuses.

The woman was much improved by the operation; her symptoms subsided. She developed practically no hernia cerebri. She died in a couple of months from extension of the tuberculosis.

We have been officially notified that the Local Government Board have established new premises for the preparation and distribution of glycerinated calf lymph for the use of public vaccinators, and have notified that all applications for calf lymph should now be addressed to the Government Lymph Establishment, Colindale Avenue, The Hyde, London, N.W.

TRANSACTIONS OF SOCIETIES.

BRITISH GYNÆCOLOGICAL SOCIETY.

Meeting held June 13th, 1907.

The President, Mr. W. Spanton, F.R.C S., in the Chair.

The President said it had been his misfortune on each occasion of their meeting to have to refer to the death of some valued Fellow of their Society. That night it was especially sad to know that their latest loss was their valued honorary president, Dr. Robert Barnes. He had a vivid recollection of the energy Dr. Barnes displayed in the formation of that Society, and probably but for his enthusiasm it would never have been founded. They were deeply indebted to him for the good work and the stimulating influence he brought to bear upon it, and deeply regretted that his declining health prevented him from taking a more active part in recent years. They deplored his loss and desired to express their sympathy with his family in their sad bereavement.

Dr. **Macnaughton-Jones** moved the following resolution of regret:—

"That we, the Fellows of the British Gynæcological Society, desire to express our feelings of deep regret at the loss the Society has sustained through the death of our Honorary President, Dr. Robert Barnes.

"To a large number of the Fellows this loss is a personal one, inasmuch as he was not only their honoured chief, but also in the years that have passed a valued counsellor and friend. His active interest in the work of the British Gynæcological Society from its foundation up to a comparatively recent time, the prestige his name and presence lent to our proceedings and meetings, and the mature judgment of one of the most cultivated minds in the profession, were of incalculable value to the Society, and materially assisted in placing it in a foremost position amongst the scientific medical societies in this country.

"We wish further to record our conviction that no obstetrical authority in England during the past century achieved so remarkable a success as a clinical teacher and lucid writer in this department of medicine. His works were classical, epoch-making, and universally read.

"In character truth-loving, fearless, honourable, and sincere, Robert Barnes has left us a bright example of the highest type of the cultured physician. Only those exceptionally gifted can hope to leave such a record behind them, but he has bequeathed to us all the precious heritage of his life's history as an example for us to imitate.

"In order to convey to his relatives in some faint and imperfect manner proof of the regard in which he was held in this Society, and to express our sympathy with them in their loss, this resolution is unanimously passed."

Dr. Macnaughton-Jones moved the resolution adding the remarks that will be found on page 711.

Dr. **Macan** said it was a great honour to be asked to second that proposal. He endorsed every word that had been said about their lamented honorary President, especially what was stated concerning his literary merits, because these particularly appealed to himself. He was sure every Fellow present would feel that they had lost one whom it would not be easy to replace.

The resolution was carried in silence.

Mr. **Mayo Robson** read a paper on "The Modern Treatment of General Peritonitis," of which the following is a short abstract:—

Mr. **Mayo Robson** said he introduced the subject of peritonitis from a general point of view. Many cases of what was described as shock were really due to sudden and rapid septic absorption and might be avoided by the adoption of preventive treatment. He had seen benefit from the use of anti-streptococcic serum, and if it was always possible to recognise the organism or organisms causing the condition, something could be done to relieve peritonitis. He advised early operation, which, if undertaken within twelve hours of the onset ought to result in saving the patient, if within twenty-four hours there was a probability that the patient's life would be saved; whilst if later there was only a bare chance. The operation should be as short as possible with little exposure of viscera, and the least amount of damage to the abdominal contents. It was not necessary to remove all the pus, as part consisted of dead cells, and the remainder of leucocytes whose office was to destroy the organisms producing the condition either directly or indirectly, and in this way assist nature in restoring the normal condition. Having removed the cause and instituted drainage they should introduce as much fluid as possible either by the rectum or transfusion, and then place the patient in a sitting posture in order that septic fluids might gravitate to the most dependent position.

Sir **William Sinclair** said puerperal peritonitis was the only form that he would refer to. At the present time everybody interested in obstetrics said no time ought to be lost. He would like to quote a case of his own. A woman in Manchester was sent to the hospital by a midwife, who had seen that something was wrong. The next day the patient was ill, had a rigor, high temperature and rapid pulse with constant vomiting and distension. He suggested that the abdomen should be drained and flushed with saline fluid. The flushing was carried on until no turbid fluid was returned; the abdomen was then closed up, the uterus curetted, swabbed and packed. The patient made a perfect recovery. The only drawback was the anæsthetic. He would advise a large dose of morphine to begin with, to be followed by alcohol, and then almost any abdominal operation could be performed, and as soon as it was over sleep would follow. That was the result of his experience of the treatment of puerperal peritonitis, and if patients were watched and treated well they would never have puerperal peritonitis.

Mr. **Charles Ryall** said that the less handling, irrigation or swabbing of the abdominal viscera, so much the better would it be for the patient. A simple laparotomy and drainage gave the most satisfactory results. As to the administration of morphine it had to be considered from the standpoint of the general practitioner and from that of the surgeon. A woman was perhaps seized with sudden pain and sent for the doctor. The pain might be due to perforation or something else and the doctor was bound to give something to relieve it. After abdominal section there always was stasis, and no doubt morphine had a tendency to increase it. The best drainage was by absorption, and the sooner they got the bowels to act the better. He believed in early evacuation of the bowels whether after a simple abdominal section as a preventive measure or after abdominal drainage as an acute measure.

Dr. **Heywood Smith** said that calomel in large doses acted like a charm, and was one of the best ways of giving relief and bringing down the temperature.

Mr. **Alban Doran** said they had a great deal more to learn about peritonitis. The great principle of treatment was to anticipate peritonitis. Where there was shock he deliberately poured in a considerable quantity of saline fluid because that was the best stimulant, far better than any venous injection and far better than the old plan of beef tea enemata. He thought when once peritonitis had appeared it was questionable whether it was advisable to give opium.

Dr. **Bedford Fenwick** said he found benefit from raising the body into a sitting posture when there seemed to be evidence of impending toxic poison. He had had several very bad septic cases in which calomel followed by sulphate of soda was given and it was found impossible to get the bowels to act. In each case the difficulty was removed by raising the patient to a sitting posture in bed. In that way distension of the colon was removed, and also to a large extent danger from upward pressure on the heart. In many cases the heart's action was more or less weakened, and if in addition there was distension of the colon, the result was frequently heart failure. Another point, and one to which he thought attention was not sufficiently directed was the real danger of too much washing out. The avoidance of drainage and washing out were points of very practical importance in treatment of cases of abdominal section.

Dr. H. **Macnaughton-Jones** said in puerperal septicæmia, his experience had been that when the opium had to be administered the case generally proved fatal. The application of ice over the whole surface of the abdomen on the appearance of symptoms of puerperal peritonitis was a most effective treatment as a preventive. Puerperal septicæmia began in the pelvis, and the object should be to limit the spread of the peritonitis. He thought that no modern surgeon in a case of approaching puerperal septicæmia would fail to see that the uterus was free from all toxic products by curettage and free flushing out of its cavity with some bactericidal fluid. As to the administration of calomel, he very much preferred small doses given at frequent intervals to large doses. The most important question of all in cases of general peritonitis was whether to open the abdomen early or only to treat the symptoms. For years he had not flushed out the abdomen except on one or two occasions and that was under very exceptional circumstances. He used mops, contusing the bowel as little as possible and using very weak solutions of formalin. When there had been an escape of fœtid pus into the peritoneal cavity, by simply opening and evacuating the pus, gently mopping out the abdominal cavity, and then employing free drainage, the patients had recovered. He preferred, in the early stages of drainage, the wide rubber tube, as a rule, to gauze. The free use of saline artificial serum by the rectum was most valuable. The first part of the paper was one of great importance, showing that shock was due to a rapid septic infection. In cases of impending shock, the better plan was sub-clavicular or sub-mammary infusion. What he learnt that evening from Mr. Robson had been the application of more recent bacteriological knowledge to the relation between shock and sepsis, and the advantage of forestalling sepsis by the methods that had been advocated. The rest of the paper had been more or less on lines on which for a number of years he had acted, and which he thought were followed by abdominal surgeons generally.

Dr. J. H. **Dauber** remarked that they had heard a great many antagonistic methods of procedure that night. There was one method alluded to that had been little discussed that night, but in which lay their real hope in the future, namely, the anti-toxin method of treatment. Most cases of peritonitis were due to absorption of some toxin and the abdomen was not always full of pus in these cases. People talked about opening the abdomen and putting in a drainage tube, but there was very often nothing to come out at all. The intestines were often merely engorged and red and that only to a slight extent. and the patient died with high or low temperature, distension or otherwise. Dr. Dauber instanced two cases in which antistreptococcic injections had apparently saved life.

The **President** said the author had shown in a lucid manner that many methods of treating peritonitis which had been in vogue were now found to be failures, and that gynæcologists had at last come back to doing as little as possible, and leaving nature to do as much as she could for them.

Mr. **Mayo Robson**, in reply. said his intention had been to bring forward a general subject that might be of interest to the Society, and which they could discuss rather from the point of view, not only of pelvic but also of general surgery. As to the use of antistreptococcal serum, if they could always know the organism with which they had to deal, if they could have the combined anti-toxins and if they could regulate the dose, doubtless they could do something to erlieve general peritonitis by injections. Certainly in puerperal peritonitis where the poison was the streptococcus they would expect to get the greatest benefit from antistreptococcal serum. He had seen benefit from serum in some of those cases. But in the greater number of cases of general peritonitis where they were dealing with the bacterium coli, sometimes with the pneumococcus, and sometimes a combination of the streptococcus with other cocci not much benefit had been apparent. He would say as the first essential, operate as early as they could. An operation for general peritonitis, though the pertonitis be diffuse, if undertaken within twelve hours of the onset, ought to result in saving the patient, if within twenty-four hours the probability was that the patient's life would be saved, if later it was a great chance as to whether life could be saved. They should do as short an operation as they could, they should take care to avoid as much as possible exposure of the viscera, they should do as little damage to the contents of the abdomen as possible, removing the causes whether the cause were the appendix or a Fallopian pus tube, or any other. If the peritonitis were due to perforation of the intestine or duodenum or stomach they should repair the perforation because while they were relieving the tension and removing the effect by drainage they wanted to avoid any other organisms being manufactured and poured into the peritoneum. Let them avoid sponging and washing, and take out as much pus as they could conveniently do, without troubling themselves if they had to leave a little behind. He warned them that they should not create more damage than the pus would do. They should, as he had just said, remove as much pus as they possibly could, because most of the pus consisted of dead cells, but the outer part of the pus consisted of living cells which actively aided Nature. After removing the cause, and draining, and helping Nature by getting in as much fluid as they could either through the rectum or by transfusion they should prop the patient up as nearly in the sitting posture as possible in order that septic fluids might gravitate to the least dangerous part of the peritoneum, from which they could be drained away.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.

The annual provincial meeting of this society was held at the County Hospital, Bedford, on June 1 th.

Dr. R. H. **Coombs** in the chair

Dr. C. O. **Hawthorne** opened a discussion on

ACUTE RHEUMATISM IN CHILDHOOD.

He referred to the considerable change which had taken place in the professional view of the age incidence, and to the special characters which distinguish the disease in children, especially the frequency of cardiac complication, which he attributed partly to the absence of restraint of the child's activities resulting from the comparative escape of the joints, and he advocated the practice of informing the parents of rheumatic families of the risks involved even in the apparently trivial illnesses of their children. He thought there was too ready a tendency to apply the term rheumatism to isolated events the nature and origin of which were obscure. He also discussed the curative and prophylactic treatment.

Dr. **Ewart** suggested that the glandular condition of early childhood was less prone to favour retardation in the joints, and the child could rid itself of disease in the joints and it would find a seat elsewhere. He suggested calomel and antiphlogistic remedies in the treatment of endocarditis.

Dr. **Morrison** referred to erythema nodosum, which is not limited to rheumatic subjects It is generally preceded by tonsilitis at an interval of ten to fourteen days. He looked upon this as its incubation period.

Dr. **Hartley** (Bedford) said that in that town, on the banks of a river, with damp climate, it would be expected that rheumatism would be very common, but his experience did not bear this out.

Dr. **Sutherland** thought it was a mistake to prolong rest in bed after active endocarditis had passed away. This was frequently done owing to the reappearance of a murmur He referred to cases of recurring subacute rheumatism, where salicylates failed. He considered there was some source of infection which was not discovered.

Dr. Cautley read a paper on

CEREBRO-SPINAL MENINGITIS.

He referred to the different varieties and the relative age incidence as an aid to diagnosis; also the relationship of the sporadic to the epidemic variety, the means of diagnosis, including lumbar puncture, &c.

Mr. Tubby read a paper on

CONTRACTION OF THE TENDO ACHILLIS

as a cause of the following symptoms: Pains in the calves, shambling gait, sprained ankle, everted feet, turning in of the toes, &c. The contraction of the calf muscles produces lessening of the angle of dorsiflexion of the foot, and shortening of the stride in walking. It is usually due to infantile paralysis, and can be remedied by lengthening the tendon.

Mr. Skelding described a case of "Bilharzia," in a boy, æt. 11, who came from Rhodesia. The symptoms were great drowsiness and hæmaturia, the ova were found in the urine.

Dr. Harry Goldsmith described a condition occurring in children, to which he gave the name of "œdema of the limbus." There were photophobia, injection of the ocular conjunctiva on which are small grey nodules, which never break down. It is rapidly cured by the yellow oxide of mercury ointment.

Clinical cases, pathological and microscopical specimens, and skiagrams were shown by Drs. Goldsmith, Ross, Coates, Phillips, Waller; and by Messrs. Johnson, Sharpin, Skalding, Nash, and Verry.

After the proceedings a well-attended dinner was held at the Swan Hotel, Mr. Clement Lucas being in the chair.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

GERMANY.

Berlin, June 23rd, 1907.

THE LATE PROFESSOR VON BERGMANN.

A commemoration celebration in memory of Ernst von Bergmann is to be held in Berlin on June 29th. Various societies, such as that for post-graduates, that for first-aid and the Aerzte-Kammer of Berlin and Brandenburg have united for the purpose, and invitations to be present will be sent to all scientific societies and other institutions with which the deceased was at all closely associated.

At the Medizinsche Gesellschaft Hr. H. Nicolai described a process by which a

Graphic Representation of the Heart's Action

could be shown. A platinum wire, freely moving between the poles of an electro-magnet is deflected by the strength of the current passing through, and the deflections are fixed on a photographic plate. The experiment was first performed and proof shown on the exposed heart of the dog and afterwards on the living subject.

Hr. Kraus saw an expression of a condition of excitement in the registering of the stream of action of the heart. He showed a large series of curves that he had taken of healthy and diseased hearts. He believed the procedure had an important practical future before it; as it was delicate and exact, and did not call for exertion on the part of the patient. Naturally a good deal would have to be done in the way of study and experiment before results free from ambiguity could be reached.

At the sitting on June 5th Hr. Toby Cohn showed a woman, æt. 64, whose history revealed nothing special, particularly as regarded syphilis. For from 10 to 12 years a great increase in size had taken place in her head that, previous to this, had been normal. Its circumference was now 68 cm. The surface was smooth. Large sinuous and dilated arteries were present over the temples; they pulsated freely. Subjectively there were noises in the ears and some loss of hearing power. It was a case of osteitis deformans (Paget) of the skull, not of leontiasis, as the skull was everywhere smooth. This was shown by the Röntgen image, that showed also enormous thickening of the bony skull.

Hr. J. Israel showed a patient in whom he had diagnosed

Calculus of a Horseshoe Kidney

from palpation. Six years ago the patient began with attacks of colic in the right side. The speaker could then by palpation recognise the connecting part between the kidneys, and diagnosed a horseshoe kidney; at the same time he felt a hard movable body on the right side which was painful on pressure. Palpation always brought on hæmaturia. He exposed the kidney through a large opening, opened the pelvis, removed the stone, and sutured the renal pelvis by a triple row of sutures. Healing *per primam*. Two years later there was pain on the left side. The left kidney was not so readily palpable. This time he made a transperitoneal opening, again removed a a stone after opening the pelvis of the kidney, closed up the wound; the patient recovering. The urine however, still remained thick and the pyelitis continued. Last April the pain was again so severe that the patient presented herself again. The speaker now felt a large calculus with enlarged renal pelvis. He made renal opening on the left side, opened up the kidney extra-peritoneally and removed a rather large stone after incising the kidney. The kidney parenchyma was brought together by suture, the pelvis drained and complete disappearance of the pyelitis followed.

Hr. Grünbaum showed a case of

Primary Carcinoma of the Vermiform Appendix.

The patient was a young girl who had had extirpation of the ovaries and tubes performed in Landau's Klinik for suppuration. At the operation a carcinoma was discovered on the vermiform appendix. She had passed through two attacks of appendicitis shortly before this. The appendix was attached It was the second case of the kind that had been seen in Landau's Klinik during the past year. The process was quite normal at the base, but showed a thickening the size of a cherry at the tip; there were no nodules on the serous surface. The growth was first recognised to be carcinomatous on microscopical examination.

The observation showed how important it was to examine the vermiform process whenever laparotomy was being performed and remove it if it showed signs of any change.

At the Verein für Innere Medizin Hr. Blechroeder showed purpuration from a woman who had died from

Hæmorrhage from Varices of the Œsophagus.

She had been admitted into hospital five weeks before. She was very fat and a drinker. She complained of undefined abdominal pains and suffered from free bleeding from hæmorrhoids. The heart was normal, also the lungs; there was a good deal of urobiline in the urine. On Friday before there was a good deal of hæmorrhoidal bleeding, which ceased after some hours. There was thought to be cirrhosis of the liver, and the patient was put on a dry diet. The following day there was severe hæmatemesis, the heart failed and the patient sank with œdema of the lungs. The autopsy showed hæmorrhage from ruptured varices of the œsophagus. When shown—in the preparation—they appeared insignificant, and not likely to be the source of such severe hæmorrhage. These varices appeared, as was known, from backward pressure from cirrhosis of the liver and might lead to serious hæmorrhages. No varices were visible, but only the collapsed veins. Litten was the first to draw attention to the condition. The liver, spleen and œsophagus were shown, also the sawn off thigh with its red bone marrow.

AUSTRIA.

Vienna, June 23rd, 1907.

Exostosis and Chondroma.

Huberer presented a patient to the members of the Gesellschaft who had been exhibited to the same body in 1887 as a typical case of multiple enchondroma. In the course of time the man had several of these enormous swellings removed at varying intervals as they became troublesome, first commencing with the left forearm, then the right forearm, followed by the left foot. The left forearm had to be amputated at a later period. After the limbs the swellings commenced over the pelvis, upper parts of the limbs, ears, and thorax, till the whole body is now invaded by a typical form of exostosis with chondroma.

Syphilis Maligna Præcox.

Noble showed a patient who had scarcely been four months infected, yet widespread destruction in the tertiary form could not have caused such devastation. The phagœdenic primary sore had quite destroyed the foreskin and penis integuments, with gangrene of the glans and forepart of the corpus cavernosum and urethra. The lymphatic glands of the groin soon became confluent, infiltrating a large area and finally breaking down. This sclerotic and ulcerative condition extended even to the head. The patient was a strong well-built individual at first, but rapidly degenerated in strength and appearance. He was not addicted to drink, which confirmed the opinion that the virus was of a mixed nature rapidly developing an endotoxin which produced the rapid destruction. Throughout this brief history every effort was made by microscopic examination to discover the spirochæta bacillus in the ulceration infiltration and other integuments, but without success.

Disinfection.

Dœrr exhibited a new method of disinfecting rooms and other places by using permanganate of potash with formalin and water, formaldehyde being given off. Two kilogrammes of permanganate of potash, formalin and water cost 4 frs., sufficient to disinfect 100 cubic metres of space. The advantage of this method is cheapness; it is non-poisonous, no expensive apparatus is required, nor even special skill in operation. Weiss remarked that he exhibited an apparatus at the last sitting of the Society for disinfecting catheters and other instruments by a similar use of autan. This substance he contended was a most effectual gas in destroying malignant germs.

Escherich remarked that his experience with these substances required careful closing of doors, windows and other apertures in order to obtain the results described by their proposers, although they consider it unnecessary to take this precaution.

Flick (Gratz) usually forms this substance into a hard roll and then evaporates it when required.

Puerperal Therapy.

Alexander continued the discussion on this subject with reference to the removal of thrombi in the prevention of pyæmia and recorded forty-five cases of otitis, where he removed the thrombus with success. He was still more dogmatic on the importance of tying the jugular vein before operating on the ear, and the necessity of thorough drainage. The lateral sinus thrombi are often thread-like or punctiform producing circumscribed phlebitis. The organised thrombus is usually cylindrical closing the whole lumen of the vessel and must be removed entirely from the sinus by enucleation. The jugular thrombi, however, are most irregular in shape and size, and common in the pyæmia from otitis. The mortality by this operation has been reduced from 81 per cent. to 22 per cent., and the meningitis or purulent encephalitis from 77 per cent. to 25 per cent.

Indian Medical Service.

An Examination for Commissions in the Indian Medical Service will be held in London on Tuesday, July 23rd, 1907, and the four following days. Particulars regarding pay, promotion, etc., in the Service and the necessary forms of application can be obtained from the Military Secretary, India Office, London.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

BELFAST.

The Treatment of Consumption.—At a special meeting of the City Council held last week the arrangement already mentioned in this column was ratified, the Council to have at their disposal 25 beds in the Forster Green Hospital, paying 35s. per week per bed occupied. The arrangement had been suggested by the Public Health Committee, but was not accepted by the Corporation without prolonged discussion, some of the members being keen to start at once to the erection of a municipal sanatorium. The arguments against this are several; one is the fact that the Workhouse sanatorium is only just started, and time should be given to see how it works before another is launched in Belfast. Another reason is that in the course of a few years the Forster Green Hospital will come into several large sums of money, and will be enabled greatly to extend the accommodation of the hospital, so that a municipal sanatorium may not be needed. It seems an exceedingly sensible thing, then, to adopt the course that has been decided upon, for the agreement is for ten years, which will allow the Corporation to see how things work, and will also make it worth while for the authorities of the Forster Green Hospital to provide the extra accommodation. The only point on which no information is yet forthcoming is the position of the honorary medical staff towards the Corporation patients.

Cerebro-Spinal Meningitis.—The number of cases of this disease notified last week rose slightly, being 17 as against 13 the week before. The deaths numbered 15, being 5 more than the week before. Of the 81 patients in Purdysburn fever hospital, 36 are suffering from cerebro-spinal fever.

Typhus Fever in Newry.—The town of Newry, in co. Down, is at present suffering from rather a severe outbreak of typhus. There have been about six deaths, including that of Dr. J. J. O'Hare, a young practitioner only qualified five years ago. Dr. Clibborn, the Local Government Board Inspector, is inquiring into the circumstances of the epidemic, and the Public Health Committee has decided to utilise the baths in Canal Street as an isolation hospital, as there is no room in the Workhouse hospital.

Ulster Medical Society.—The annual meeting of this Society was held in the Medical Institute, Belfast, on Thursday evening, the 20th inst., the President, Dr. D. P. Gaussen, in the chair. The annual report read by Dr. Howard Stevenson, the hon. secretary, and the statement of accounts presented by the Hon. Treasurer, Dr. Fielden, showed the society to be in a flourishing condition. The total membership numbering 175. On the motion of the secretary, an alteration was made in the rules to facilitate the admission of officers in the various public services who may only be stationed or on leave in Belfast for short periods. The following were elected office-bearers for the Session 1907-8:—President, Dr. John McCaw; vice-presidents, Dr. Wallace, Knockahollet, co. Antrim; and Mr. A. Fullerton; hon. secretary, Dr. Howard Stevenson; Hon. treasurer, Dr. Victor Fielden; hon. editorial secretary, Dr. Rankin; hon. librarian, Dr. Story; Council, Drs. Craig, Houston, Johnstone, McQuitty, Robb, and Professor Symmers, with the Trustees of the Institute, Drs. John Campbell, Dempsey, Lindsay, McCaw, Mitchell, Nelson, and Cecil Shaw. The President-elect, Dr. John McCaw, is senior physician to the Belfast Hospital for Sick Children, and has for many years taken an active part in the work of the Society, having been successively honorary secretary, treasurer and vice-president. It was announced at the meeting that the Lindsay Challenge Golf Cup will be played for on the Malone Links, Belfast, on Thursday, July 4th. It is hoped that some of the country practitioners in town for the Post-Graduate Course at the Royal Victoria

Hospital may enter for the competition. It is played by strokes under handicap (not exceeding 20), the first eight to qualify to play off by holes.

LETTERS TO THE EDITOR.

PHYSIOLOGY AND PRACTICE.

To the Editor of The Medical Press and Circular.

Sir,—The opinions which I wish to express on the above subject have not been hastily or summarily formed, but are the outcome of several years' experience in extensive practice, as well as in many physiological laboratories. It is often difficult or impossible to convince others of certain things of which we are ourselves fully convinced. While believing that such attempt at conviction in the present instance is unnecessary so far as the majority of your readers are concerned, yet I write with the object of advancing a plea for a wider and more careful study of physiological processes than is generally devoted to them by the average practitioner.

It is unnecessary to mention in detail the simple methods which we learned, or thought we learned, as students, and which one sees forgotten or neglected in practice. Yet these methods are not only useful but absolutely essential to correct observation and treatment of morbid conditions. Quite a large proportion of students who, in their second or third examinations, have successfully negotiated such obstacles as herone bases and amino-acids, or steered clear of such quicksands as balance-sheets and diet-tables, utter a fervent "Deo Gratias" for having done with the disagreeable subject for ever. Many, it is true, even when hampered by difficulties, persevere in maintaining the knowledge acquired because they appreciate its value.

Anything like adverse criticism of the present-day teaching of physiology is far from my mind. But I would suggest that a more systematic reference by teachers to the all-important practical bearing of the subject, to the application of the methods in the treatment of disease, would help materially to allay the vicious tendency of the student to study this branch of science purely for examination purposes.

The annual introductory addresses at the medical schools are interesting and instructive. Perhaps they would be no less so—even a little more so—if prefaced or concluded by an appeal to students to bear in mind that the study of physiology is the backbone of the study of medicine, that it has not been introduced into the medical curriculum to test their powers of memory at examinations, that it will be of vital importance in practice, and that it must be a matter of life-long study. It is not enough, as it may be argued, to read isolated physiological facts in medical text-books. It is the interest which the practitioner takes in the subject as a whole which prevents him from overlooking its facts. Many medical men, of course, cannot do regular, or irregular, work in a laboratory; but an occasional short course is within the reach of most practitioners. They would be immensely pleased with it.

In conclusion, let me state, even at the cost of repetition, that an exact knowledge of normal functions is wholly essential to correct observation of pathological processes and to sound treatment of the same. Failing this, we may be "so blinded as to overlook the truth which is tumbling out, so to speak, at our feet."

Was du lerns't, das lerne recht;
Was du mach, st, das mach' nicht slecht!

I am, Sir, yours truly,
D. T Barry, M.D., F.R.C.S.Eng.,
Demonstrator of Physiology, Queen's College, Cork.

QUACKERY AND PRACTICE BY COMPANIES.

To the Editor of The Medical Press and Circular.

Sir,—The Bill for the prevention of illegal practice under the cloak of the Companies Acts has been duly examined by the Committee of the House of Lords, and no doubt some of its promoters of an optimistic temperament look forward with confidence to its acceptance by Parliament during the present and some future session. I venture to assert that it is really a matter of very little importance whether the Bill becomes law or not. It could have no appreciable effect upon quackery. It would no doubt put to inconvenience a small proportion of fraudulent quacks—certainly not more than one in a hundred of the mass—but it would not hinder them for one day in the pursuit of their nefarious games. To illustrate this I send enclosed some dozen advertisements from London and country papers, including to its shame, be it always said, the *Times*, which, I point out by the way, seems sinking lower and lower beneath the high standard of conduct it formerly maintained. To legislate against fraudulent practice must prove futile unless the blow aimed cannot be evaded; and it is to me amazing that the promoters of the present Bill should not have recognised the weakness of the weapon they were forging, and that they should have incurred the waste of force involved. They can have known very little about quacks, their cunning and resourcefulness. They seem not to have recognised that they could not possibly establish indisputably the case for legislation by the method adopted, that they could not demonstrate clearly that the system they wished to put a stop to was a system of cruel and shameful fraud. Tinkering with the law in such a fashion will never do much good. The present effort has resulted, no doubt, in the enlightenment of a few Peers as to the seamy side of medical life, but it is certain that beyond this few, none of our legislation in either house have been made a jot less ignorant than they have always been on this subject. If the labours which have been devoted to this futile attempt had been directed to the promotion of a Royal Commission the whole story of quackery might have been unfolded, the chapter relating to medical and dental companies would in due course have been also laid bare; the directors of the companies could have been compelled to appear to refute the charges which would have been made against them, and to justify their existence before a competent tribunal. If I speak confidently or dogmatically it is, at any rate, after more than thirty years study of the subject; and this latest episode has further strengthened my conviction that the only way towards satisfactory medical law reform lies through the medium of a Royal Commission. I trust you will continue to keep this question to the front until it receives full recognition from the profession.

I am, Sir, yours truly,
Henry Sewill.

June 16th, 1907.

OBITUARY.

PROFESSOR EDWARD HALLARAN BENNETT.

We announce with regret the death of Professor Edward Hallaran Bennett, which took place at his residence, 26 Lower Fitzwilliam Street, Dublin, on Friday, June 21st. His death was not unexpected, as he had been in failing health for a long time. During the past six weeks he became progressively weaker, and when the end came he peacefully passed away. The primary cause of his death was apparently a form of anæmia. More than two years ago he found himself unequal to the task of delivering his professional lectures in Trinity College, and it became necessary to appoint a deputy to carry on his work. He continued, however, to act as surgeon to Sir Patrick Dun's Hospital until October of last year, but his strength then began to fail so rapidly that he felt obliged to resign his hospital appointment. Indeed from this time onwards he was confined entirely to the house.

Edward H. Bennett was fifth son of the late Robert Bennett, Barrister-at-Law and Recorder of Cork. He was born in that city on April 9th, 1837. His mother was a daughter of William Sanders Hallaran, M.D., of Cork, who published some medical works of repute.

Professor Bennett received his early education at Hamblin's School in Cork, but was subsequently educated at the Academical Institute, Harcourt Street, Dublin. From this institution he entered Trinity College, Dublin, and graduated in 1859 as B.A., M.D., M.Ch. He obtained the fellowship of the Royal College of Surgeons of Ireland in August, 1863. He became University Anatomist in 1864, his predecessor being the late Dr. John Kellock Barton. On the death of Professor R. W. Smith in the year 1873 he was appointed to the chair of surgery in Trinity College. Both appointments carried with them a surgeoncy to Sir Patrick Dun's Hospital. In subsequent years he was made Consulting Surgeon to Dr. Stevens' Hospital, to the Royal Victoria Eye and Ear Hospital, and to the Dental Hospital of Ireland. In the year 1884 he became President of the Royal College of Surgeons in Ireland, and in the year 1900 the honorary fellowship of the Royal College of Surgeons in England was conferred upon him.

Professor Bennett took a deep interest in the Royal Academy of Medicine in Ireland, and acted as the president from 1897 to 1900. During the viceroyalty of the Earl of Dudley he was surgeon-in-ordinary to his Excellency the Lord Lieutenant of Ireland. He represented Dublin University on the General Medical Council for several years, but resigned the appointment two years ago when he felt unable to attend the Council meetings.

Edward Bennett was a man possessed of an attractive personality. With students of medicine he was immensely popular, and generations of undergraduates who attended his lectures and surgical demonstrations were wont to allude to him as "the Boss." They listened to his stories with keen delight, and wondered at his intimate knowledge of surgical lore and his familiarity with the works of the great surgical masters of the past.

As a hospital teacher Bennett was eagerly listened to by his students. His diagnoses were often brilliant, and prior to the X-Ray era his wonderful diagnostic skill in obscure cases of fracture and dislocations was widely recognised. The character of the man was most clearly revealed in his hospital work, and many of those who in byegone years accompanied him on his rounds through the wards will remember the considerate regard which he evinced for his patients. For all he had a pleasant word, a genial smile and full-hearted sympathy. By his juvenile patients especially he was beloved, and he loved them. Indeed it was remarkable how quickly he succeeded in gaining their confidence and setting their fears at rest.

As a surgeon Professor Bennett may justly be regarded as a representative of the older school, although he was quick to estimate the value of modern methods and carry them into execution. It is generally admitted that he was the first to introduce Listerism into Dublin. As a young man he came into close association with Professor Robert William Smith, and it was through the influence of this great surgeon that Bennett acquired such a deep interest in all matters appertaining to injuries and diseases of bones and joints. He made this branch of surgery his hobby, and he has left behind him in the surgical Museum of Trinity College a priceless collection of specimens. Whenever Professor Bennett made a communication on any subject bearing on osseous pathology he showed himself a master of his subject, and made it replete with interest for his hearers. He made many and valuable contributions to surgical literature, the principal of which dealt with the subject of fractures. He was the first to recognise a form of fracture implicating the base of the metacarpal bone of the thumb and in modern surgical works it is alluded to as Bennett's fracture. When he ceased active work in the University it was decided to perpetuate his memory by means of a suitable memorial. A large sum of money was contributed by his old pupils, a portion of which was set aside to found a money prize for the candidate who obtained the surgical travelling prize. With the remainder two medallions, representing Professor Bennett's profile, were struck; one has been placed in the surgical theatre of the medical school in which he lectured; the other occupies a conspicuous place in the hall of Sir Patrick Dun's Hospital. In addition to the medallions, dies were struck for a Bennett medal to be awarded to the student coming second in order of merit at the surgical travelling prize examination. The medal is of bronze. On one side Professor Bennett's head is seen in profile and the following inscription—"In Honorem Edward Hallaran Bennett, Prof. Chir., 1906." On the opposite side is represented the metacarpal bone of the thumb showing the fracture associated with his name and the inscription—"Viri In Fractis Ossibus Collocandis Solleritissimi."

As a friend Bennett endeared himself to all who knew him. Beneath a somewhat blunt exterior there lay a kindly disposition and a depth of geniality which few could fail to appreciate. He was a loyal colleague, and one with whom it was not merely a pleasure, but also an honour to be associated. He will long be remembered as a warm friend, a delightful companion, and an ornament to the surgical profession.

The funeral took place on Monday, June 24th, and was attended by a large and representative gathering Professor Bennett's late colleagues in the medical school of Trinity College and a large body of students in collegiate dress followed the *cortège* to Mount Jerome Cemetery. The President and members of Council of the Royal College of Surgeons, and the President and many of the Fellows of the Royal College of Physicians attended to pay the last tribute of respect to the memory of one for whom they entertained a genuine regard.

SPECIAL ARTICLE.

THE LATE ROBERT BARNES, M.D., F.R.C.P., F.R.C.S.Eng. (a)

By H. MACNAUGHTON-JONES, M.D.

It may be truthfully said of our late Honorary President, Dr. Robert Barnes, "Nullum quod tetigit non ornavit," and it is a proud boast of our Society that, from its inception, his name has been inseparably linked with its history. It was characteristic of Robert Barnes that he was ever on the side of progress and advance from the time that he began life as a general practitioner, up to his latest years. It is an interesting fact in his history that he was the son of the Founder of the Gardens of the Royal Botanical Society of London, and here there may have been a hereditary link that connected father and son in their love of nature and the natural sciences, as Robert Barnes was a Vice-President of the Meteorological Society and Fellow of the Linnean and Geographical Societies. The City of Norwich has the honour of having been his birthplace, as it has of being that of many other distinguished men in our profession. Having begun life in that best of all schools for preparation for devotion to a special study, that of a general practitioner, Barnes was one of those who waited not on opportunities, but created them; and therefore there was a good deal of struggle in his early professional days, both when he was studying in Paris in 1842, and after his return to London. As with many another worker he had to a great extent to rely on his pen. His acquaintance with languages began during his studies when at school at Bruges, and afterwards in Paris—a knowledge which was of material assistance to him in after life. His extensive practical acquaintance with obstetrics may be estimated by the mere recital of the various hospitals in the Metropolis in which he served—as obstetric physician to the London Hospital, St. Thomas's Hospital, and his own old hospital, St. George's, besides being consulting physician to the Royal Maternity Charity, the East London Hospital for Children, and the Hospital for Diseases of Women and Children, and the Seamen's Hospital.

(a) An address delivered at the British Gynæcological Society June 13th, 1907.

His reputation abroad was shown by the honours conferred on him by his election to various foreign societies, and the estimation in which he was held at home by his holding the Honorary Fellowship of the Royal College of Surgeons of England, the Honorary Fellowship of the College of Physicians of Ireland, and the Honorary Fellowship of the Royal Medical and Chirurgical Society, as well as of the Medical Society of London and the Obstetrical Society of Edinburgh. He was Honorary President of the Glasgow Obstetrical and Gynæcological Society, and Honorary President of three International Congresses of Obstetrics and Gynæcology—Bordeaux, Geneva, and Amsterdam. He was one of the original Fellows of the Obstetrical Society of London, and followed Henry Oldham as President in the year 1865, the first two occupants of the chair being Rigby and Tyler Smith.

In medical literature Barnes held much the same position in regard to his style of writing in obstetric medicine that Watson did in his "Principles and Practice of Physic." Clear in expression, leaving no ambiguity on the mind of the reader either as to his own opinion or the definite directions given regarding practice, yet withal in language simple but classical, we may truly say that his writings showed the man. The *Lancet* has paid a graceful tribute to the value of his contributions to, and his long association with that journal. His "System of Obstetric Medicine and Surgery," written in conjunction with his son, Dr. Fancourt Barnes, appeared at a time when gynæcology was emerging out of chaos, and passing from what we might term its colloid into the earlier stages of a crystalloid state, and though full of the most valuable clinical instruction, necessarily suffered from the rapid advances, especially of an operative nature, which practically made a new science of gynæcology in the years immediately succeeding its production.

Different has it been with his "Lectures on Obstetric Operations," of which Pajot, in his introduction to the French edition said: "The clearness of the style is perfect. . . . Clinical truths are sown over every page of this book. . . . Great questions in obstetrics are treated with accurate good sense . . . at each instant by some remark or other is revealed a superior mind ripened by having seen much and meditated much."

Having availed myself largely of these lectures, which appeared first in the same year that I obtained my University Chair, for which I had the honour to be recommended by the writer, I found them invaluable for teaching purposes, and I think that you will agree with me in the statement that no more concise, lucid and safe work on operative obstetrics has ever issued from an English pen. His name will ever be associated with the advocacy of the use of the long forceps, and the form of it which he devised, as with mechanical dilatation of the cervix in labour, and the management of placenta prævia.

In Great Britain there are some names which stand out as sign-posts marking the various stages in the progress of obstetrics, such as those of Smellie, Oulde, Chamberlain, Denman, Rigby, Simpson, McClintock, and Matthews Duncan, and the last of these is that of Barnes. He was one of those fortunate favourites of the gods for whom so great was their love that they endowed him with perpetual youth. Only last year he attended in the gardens founded by his father the meeting of the provincial Fellows of our Society called together to discuss with those of the Metropolis the scheme for amalgamation with the Obstetrical Society of London in the formation of the new section in the Royal Society of Medicine, and one of the last acts of our Council was to make one of our conditions for amalgamation that he should be elected an Honorary Fellow of the new society.

"Les dieux," says M. Jaccoud, "qui habitent l'Olympe boréal doivent à la céleste vertu des pommes d'or du Walhalla le mystérieux privilège d'échapper aux atteintes de l'age ; mais une condition absolue domine et commande cette apparente immortalité : l'usage de ces fruits inestimable doit etre quotidien ; s'il est un seul jour suspendu, le miracle cesse, et la sénilité conjurée reprend tous ses droits." (*a*)

After a lifetime of medical practice, at an age which few are permitted to reach, retaining health and faculties, he died in full mental vigour, having led a life :

Unwarped by bias, and from rancour free,
Above the trivial brawls that envy breeds;
His mind an index of a soul that soared
Outside the petty bonds of hostile creeds.
Through life his straight and even course he kept
His goal the truth ; and this the path he trod—
The highway Science marks for suffering's needs,
And Duty paves with stones rough hewn by God.

REVIEWS OF BOOKS.

LLOYD ON HAY FEVER (*b*).

THIS little book contains a clearly written account of the conditions known as hay fever and hay asthma. A brief *resume* of the opinions of leading writers on the subject discloses the belief that hay fever may be caused by a great variety of excitants other than pollen. The author discussed fully the action of pollen, of dust, and of temperature, to each of which he assigns a definite place in the ætiology of the disorder. Among predisposing causes he mentions the neurotic element, and quotes the interesting case in which an attack was induced by smelling an artificial flower. Another predisposing condition is that of adenoids. An interesting view of the pathology of hay fever is that which classes it among the neuroses for the reason that its principal manifestations are the result of a temporary arrest of vaso-motor control of the vessels of the nasal mucous membrane. Since Voltoline's clinical case of asthma was cured by the removal of a nasal polypus, the belief has become generally established that a certain percentage of cases of asthma are due to intra-nasal disease. The author is specially good and clear in dealing with the question of treatment, whether connected with some special pathological nasal condition or otherwise. He finishes by giving notes of a number of clinical cases and their practical treatment. Mr. Lloyd's little volume will be found of service to practitioners who are called upon to treat the troublesome minor ailment with which it deals.

WEBER ON MINERAL WATERS AND HEALTH RESORTS. (a)

The publication of a new and greatly enlarged edition of this well-known book of reference is sufficient evidence of the important position now occupied by physical therapeutics in modern treatment. In chronic and even in some acute maladies the question of environment is a large and important one, and it is becoming recognised more and more that the conditions of life, occupation, and surroundings in which a malady is engendered are not exactly the conditions favourable to recovery. For this, among other reasons, the question of "Where shall I send my patient?" is one often cropping up in the mind of the busy practitioner, and the possession of such a mass of information as is contained in this volume, upon the many possible places to which he may be advised to go, cannot fail to be of the greatest value. The ground covered is so extensive, and the number of health-resorts is so large, that the process of selection becomes more and more bewildering. Indeed, the time is not distant, surely, when more attention will be devoted to Balneology and Climatology in the medical curriculum, and an elementary knowledge of the subject become necessary before qualification. It is surely as important that a patient should be sent to the right health resort as that he should have the correct medicine prescribed for him, and when one has heard the maledictions heaped on the head of the unfortunate young practitioner who has sent his patient to the slushy discomforts of St. Moritz in April or October, or to the tropical heats of, say, Montreux in August, the appearance of a reliable book of reference such as this cannot fail to find a welcome. In looking at a book of reference of this sort, perhaps the best way of testing its value is to look up a few places one knows well, and to find out how the information given accords with one's own knowledge. Tested on these lines, the details given of many health stations of the best class, and of others comparatively insignificant, are found to be fairly accurate. During the last few years, a great deal of attention has been directed to our own health resorts, and it has repeatedly been pointed out that there are comparatively few advantages to be gained at a foreign spa which cannot be obtained just as well or better in our own country. When one considers the sea-crossing, the long and fatiguing railway journey, and the discomforts of most continental hotels it is obvious that it is only the invalid of the most robust order who should be sent so far from home; and yet one meets with English invalids at Carlsbad, Homburg, and Wiesbaden, and especially at Nauheim, in the most desperate condition, sent out, too, by "my London physician," and finding themselves in a crowded health resort, and submitted to the routine treatment of medical men, the most popular of whom at each resort are so overworked that they have not the time at their disposal to give the attention such cases demand. For these, at least, a home resort would be infinitely preferable, and, as the continental spas are described and recommended with such detail, it is disappointing to find that the home spas are but scantily noticed, and where they are alluded to it is, in many instances, but to damn them with faint praise. Take, for instance, Woodhall Spa (p. 265). The statement is made that it has much weaker brine than two other places; that it is *only* 40 feet above sea level, and that "though by many it would be called a dull place to stay at, others are likely to be well suited there."

Tunbridge Wells' Chaylbeate water is very poor in carbonic acid gas, and cannot be ranked with the waters of Spa in Belgium, Schwalbach in Germany, &c. Matlock Bath, which has during the last few years greatly increased its bathing facilities in connection with one of the three important warm springs in the country, is described as "less bracing" than some other places, and the properties of its waters hardly noticed. In reading through these Inland Spas, it would appear that nothing that could be advanced to their disparagement has been omitted, whereas in some of the smallest of the German or other Continental spas but little is said of their disadvantages, the statements of the Kur-verein being usually accepted and endorsed.

Again, in the "Localities Recommended for Various Complaints," the Riviera and Egypt, and Egypt and the Riviera, appear on nearly every page; Harrogate and Llandrindod Wells are mentioned once or twice, but nearly all the other British health resorts are conspicuous by their absence, while the German, Belgian, French, and Swiss "cure" places are freely recommended.

There is so much that is useful and of real value in this new edition that it is to be hoped that in the next one the advantages of our own health stations will be made more prominent, and that by this means some of the enormous sums taken abroad annually to the Continent may be diverted to them, so that they may add to their attractions, and become less "dull" and unpopular.

THE ALCOHOL PROBLEM (a).

It is well that the much discussed and many-sided drink question should now be receiving that impartial and unprejudiced scientific study which only medical observers are in a position to afford. The problem is essentially a medico-sociological one, and all theories and measures of reform which neglect to recognise it as such must of necessity be lacking in the fundamental conception of the subject. Among recent works dealing with alcohol and alcoholism Dr. Sullivan's able monograph must be accorded a foremost place. It is written in a lucid and attractive style, its diction is that of the long experienced and thoroughly trained scientific observer, its matter is well arranged and is not lacking in originality and suggestiveness; in short, it is a serious and sensible contribution to a subject peculiarly intricate and perplexing, and abounding in difficulties and misunderstandings, which should be read and carefully analysed by every medical practitioner and all would-be reformers. Dr. Sullivan ably summarises the fundamental data of the drink question; presenting careful sections on the physiological action of alcohol, the pathology of chronic alcoholism, the social causes of intemperance, the relation of alcoholism to suicide, crime, insanity and human degeneration. The chief value of the work is that it definitely demonstrates that at least in this country intemperance as a social problem depends on the prevalence of industrial drinking. This is a conception which has received far too little consideration, and it may be hoped that Dr. Sullivan's able contribution will do much to direct measures of so-called temperance reform along rational lines. The appearance of this work is opportune, and it should do much to dissipate the prejudice and ignorance still existing among members of the medical and other professions, and occasionally finding expression in ludicrous and unscientific manifestos and other undesirable forms of publication.

Trinity College, Dublin.

During Trinity Term, 1907, Mr. Cecil Scaife passed (Part II.) in Public Health; and the following candidates passed the Final Medical Examination (Part II), (names arranged in order of merit): William Pearson, (passed on High Marks), Richard G. S. Gregg, Robert E. Wright, William A. R. Spong, Henry de C. Dillon, James G. M. Moloney, William E. M. Armstrong, Wilfrid J. Dunn, Thomas P. S. Eves, Henry P. Hart, Frederick Stevenson, Francis O'B. Kennedy, James D. K. Roche, Oliver St. J. Gogarty, James C. C. Hogan, Charles H. O'Rorke, Ernest T. Jameson, Joseph C. A. Ridgway, Edmond H. Sheehan, James R. Yourell, Archibald L. Robinson, Wallace D. Mitchell.

DISEASES OF THE SKIN (*a*).

Dr. Meachen has endeavoured in this little book to render the nursing of skin cases more popular by diffusing more knowledge as to their nature. The book is primarily intended for nurses, consequently only the commoner forms of disease are described, and the general principles which underlie their management. We believe, however, that the book will be of considerable use to students beginning the study of dermatology and help them to acquire, what many of them are sadly deficient in, a general knowledge of the principles of the subject. The chapter on classification and the description of the different kinds of lesions is particularly useful in this connection, as is also the chapter on the principles of treatment. It would, we believe, have been an advantage had the author described a method of case taking in skin diseases and illustrated it by examples from some of the commoner forms, for it is in this respect that we have found students as a rule most deficient. Dermatology can only be learned in the clinic, but in order that the beginner may get the best advantage from the attendance at the clinic he must be able to observe and describe accurately the cases which he sees there. We recommend Dr. Meachen's book not only to nurses but also to students, and believe that a careful study of it will be of more advantage to them than many of the more pretentious works on dermatology.

FORMULAIRE FRANCAIS (*b*)

Each year this excellent annual grows in favour with both British and Continental physicians. The experience of many years has enabled the author to produce a book which is particularly suited for the requirements of the practitioner. All the new remedies are treated of with sufficient fulness both from the chemical and the therapeutic standpoints, and the untoward results of the use of the substance as well as its valuable properties are fairly told. There is no annual we prize more highly than M. H. Bocquillon-Limousin's dainty little volume.

OPERATIVE GYNÆCOLOGY (*c*).

The great work, "Operative Gynæcology," which Professor Kelly gave us nine years ago, has undergone a very careful revision. New chapters have been added, and some material found in the first edition has been omitted. Nevertheless, despite the fact of much additional matter, the work is more concise and explanatory, and has been thoroughly brought up to the standard that modern gynæcology requires. The illustrations which formed such a feature in the original edition retain their high grade of excellence, and while many have been left out as being perhaps unnecessary, a large number have been inserted which are admirably chosen and executed. In Chapter V. very full descriptions are given of the various methods of examining a patient. The author has, moreover, introduced a new method which is carried out by means of an instrument he has himself devised "for the purpose of measuring resistances in the abdominal wall, so as to differentiate between the firmer parts in relation to a tumour lying behind and the more yielding surrounding areas." This instrument he calls the Piezometer, and claims for it further a considerable value in detecting the amount of pressure necessary to produce pain in the appendical region as compared with the opposite side. There is an illustration of the instrument, and one showing its use in the latter capacity. Three new chapters are inserted at this stage dealing respectively with "Local and Palliative Treatment," "Menstruation and its Anomalies," and "Uterine Displacements and Their Treatment by Pessaries." The articles are short and the subjects far too sketchily written to be of great value. It is, however, of interest to note that Professor Kelly has a word to say on the pessary's behalf. The chapter dealing with repairs of perinæum and relaxed outlet is most explicit, and amply illustrated making each step in the operation perfectly clear. When we come to the chapters devoted to the affections of the urethra and bladder and the ureter, we find the author at his best. This portion has been for the most part rewritten, and the insertion of several new illustrations render it more valuable When we come to consider what we owe to Professor Kelly's work upon the bladder and the ureter, anything like criticism seems almost to savour of impertinence. A short chapter on X-rays as a means of detecting calculi is entirely new, and comes from the pen of Dr. F. H. Baetjer. The second volume contains most of the major operative work, and is in general a masterly exposition. It must be remembered, however, that many methods known to and recognised by all gynæcologists are not made mention of. This is because Professor Kelly describes "Operative Gynæcology" as it is seen by him to answer best, and, in spite of these omissions, his work stands as the first on the subject in the English language.

PLAGUE (*a*).

Some six or seven years ago Dr. Ishigami, of Osaka, published hurriedly, but under the supervision of Professor Kitasato, a little book on plague, intended to be of assistance to medical practitioners who were without any text-book on the disease in the Japanese language. This book has been translated, enlarged, and illustrated by Dr. Donald MacDonald, of Adelaide. It is very difficult to disentangle the original work of Dr. Ishigami from the additions of Dr. MacDonald. The process of doing so, indeed, appears to be the winnowing of wheat from the chaff. Dr. Ishigami's handbook, as far as we can judge, was excellent in its way—terse, clear, informative, and possibly, in the original, readable. He discusses the subject from every point of view—historical, clinical, pathological, epidemiological, and, as might be expected from a pupil of Kitasato, he is thoroughly scientific in his method of thought. The book, however, as Dr. Ishigami admits with all modesty, was hurriedly written, and by no means complete. Nevertheless, it would, if carefully translated into clear English, have been of considerable value and interest to English practitioners suddenly brought into contact with plague. As it is, however, we fear that Dr. MacDonald has defeated his purpose. In his attempt to make the work complete he has added a considerable mass of material, much of it valueless in itself, and nearly all out of place in a book with Dr. Ishigami's modest purpose. Moreover, although the book is not large, and is unpleasantly printed on bad paper, it is published at an exorbitant price. Dr. MacDonald's style is slovenly, and his technical terms are not to be trusted. We take at random one or two examples which could be equalled on nearly every page:—"The trachea is generally normal in most cases" (p. 24); "the stomach is often digested in cases that have expired some time" (p. 25); "the solitary glands are always more or less tumid. They are more so in the lower part of the intestine, which are sometimes the size of a pea. As in the case of typhus, Pyer's patches are, etc.," (*loc. cit.*) The reference is, of course, to typhoid. There are several charts exhibiting the course of the disease, and these are instructive. The other illustrations are most of them useless, and some offensive. Of the latter class are three "chromo-lithographic plates," which are supposed to depict cultures of bacteria. They are, apparently, impudent advertisements for a manufacturer of patent foods. We confess that we leave the book without discovering what the translator means by "pathological horticulture," or for what purpose he introduces quotations from Ruskin, Leigh Hunt, and Keats.

THE EDINBURGH MEDICAL JOURNAL (*a*).

This half-yearly volume, representative of the medical work and thought in Edinburgh, is well up to its own average, as far as the original articles it contains are concerned. It contains thirty papers in all dealing with medical, surgical, gynæcological, and other subjects, and in addition presents some very useful summaries of the advances that have been marked in various branches of medical science. Amongst these summaries we notice articles on such important subjects as heart block; chlorides in relation to œdema; superficial reflexes; thiosinnamine injections, and many others. The critical and complete nature of these summaries renders them a most important part of these volumes, and enables the reader with comparative ease to keep himself well in touch with modern research in almost every department of practical and theoretical medicine. We have always regarded them as the best of their kind to be found in English journals, and are glad to find their character maintained. The wonder is that no journals exist given up entirely to this class of work, which it must be remembered is very different from mere précis writing, in that concentration and criticism are combined. Numerous German journals of the kind exist, and are largely bought in this country. We venture to think that an English venture of the same kind would be a profitable investment in more ways than one, provided its literature selection was sufficiently cosmopolitan, and provided that some work and thought was put into its articles. Amongst the original articles one by Dr. Meikle on "The Persistence of Bacilli in the Throats of Convalescent Diphtheria Patients," as determined by an examination of 300 patients, is a most important one. In it he draws several important conclusions, amongst which we find (1) that the diphtheria bacilli present in the throats of convalescents are generally of diminished virulence; (2) that steady antiseptic treatment tends to still further diminish the persistence of such organisms; (3) that bacilli are generally absent after three weeks from the commencement of the illness. Two important therapeutical studies are also included, one on the use of "Formic Acid in the Treatment of Diphtheria," and another on the "Salicylate Treatment of Scarlatinal Nephritis"; while amongst the surgical papers is an important personal analysis of 46 cases of perforated gastric and duodenal ulcers operated upon. The volume, in fact, contains interesting matter for all medical readers, but it is unnecessary to refer directly to its further contents.

MEDICAL LATIN (*b*).

Mr. Bennett's book on "Medical and Pharmaceutical Latin" is intended to supply a sufficient knowledge of the Latin tongue for the purposes of writing and reading prescriptions. It is quite true, as the author points out, that the writing of a prescription in language understood by the patient has certain disadvantages, of which self-drugging is not the least. The writing of elegant prescriptions is, moreover, an art for which we have the greatest respect, but it is not, as many pharmacists seem to think, the final test of an educated physician. A man may be an excellent physician and a good citizen, and still be unable to write a prescription in sound Latin. The truth is that life is getting too crowded for the writing of elegant prescriptions; as, however, the employment of drugs is every year moving more into the background in rational therapeutics, the matter is not one of much moment. Mr. Bennett's book, however, is well adapted for its purpose. It contains not only the elements of Latin grammar, but a large collection of prescriptions in Latin and English by way of illustration, and several vocabularies containing all the words likely to be met with in pharmaceutics. The book will be found of much use to dispensers, and many medical men will be glad to have it for reference.

ELEMENTS OF PHYSICS (*a*).

The growing importance of the science of physics in the treatment of disease makes it imperative that medical students at the beginning of their studies should be well grounded in the different branches of this science. Mr. Page has written this book to supply a need he has experienced, a suitable text-book for students intending to enter for the examinations of the Conjoint Board and the Society of Apothecaries. The book is further intended "to bring into prominence those branches of physics which might be useful to the student in his future career."

A careful perusal of the work shows that Mr. Page's knowledge of the average student's needs has been turned to good account, with the consequence that a subject that is generally distasteful is presented in such a manner as to lose most of its terrors. The diagrams are excellent and free from unnecessary elaboration; the idea in keeping them simple and diagrammatic being "to encourage the student to reproduce them when describing the various instruments and methods." That the matter covers the requirements of the two syllabuses goes without saying, while the simplicity of letterpress and illustrations, will, we are confident, ensure the book a warm welcome from teachers and students.

LITERARY NOTES.

We learn that a circular has been issued to the members of the Medical Profession in Ireland and England asking for support for the Irish Language Fund, and pointing out that the promotion of the Irish language should specially appeal to the medical profession, not only on the ground of its great educational value, but also from the fact that a knowledge of Irish is of great advantage to any doctor practising in an Irish-speaking district. Subscriptions may be sent to the Hon. Sec. of the Medical Committee, 32 Lower Leeson Street, Dublin.

* * *

The June number of the *Westminster Review* contains no less than three articles by medical men. Dr. James Baugh writes with information on one of the most interesting provinces of the Empire—French Canada. Dr. J. Haddon takes up the cudgels on behalf of vegetarianism. He thinks there is a close relation "between the nerves of the stomach and centres on which life seems to depend." He adds that physiology has not yet discovered where these centres are. Dr. John Knott belabours with his usual powers an unfortunate upholder of the doctrines of Christian Science.

* * *

The late Mr. Richard Carmichael, having bequeathed to the Royal College of Surgeons, Ireland, a sum of money for the purpose of founding prizes for essays upon certain subjects specified by him, the President and Council give notice that, on the first Thursday in November, 1908, they will proceed to adjudge a prize of £120 for the best essay that may be presented to them in accordance with the following instructions prescribed by Mr. Carmichael:—(1) The state of the medical profession in its different departments of physic, surgery, and pharmacy, in Great Britain and Ireland, at the time of the writing of these prize essays. (2) The state of the hospitals and schools of medicine, surgery, and pharmacy. (3) The state and mode of examination, or of testing the qualifications of candidates of the different licensing colleges or corporations of medicine, surgery, and pharmacy. Under these heads the authors should make such suggestions as may occur to them respecting the improvement of the profession, with the view of rendering it more useful to the public, and a more respectable body than it is at present. In these

(*b*) "Medical and Pharmaceutical Latin for Students of Pharmacy and Medicine." By Reginald R. Bennett. With an Introduction by Henry G. Greenish, F.I.C., F.L.S. London: J. and A. Churchill. 1906. Pp. xii. and 442.

(*a*) "Elements of Physics for Medical Students." By Frederic James M. Page, B.Sc. (Lond.), F.I.C., A.R.S.M., Lecturer on Physics and Chemistry to the London Hospital Medical College, Examiner in Physics and Chemistry to the Society of Apothecaries of London. 1907. Price 5s. Pp. 288 and xvi., with a coloured frontispiece and 230 figures in the text. London: Cassell and Company, Ltd.

suggestions the authors must consider the preliminary and moral education of medical and surgical students, the mode of conducting their professional studies, and of testing the qualifications of candidates by the licensing bodies. Each essay is to be distinguished by a device or motto, and accompanied by a sealed packet, containing the name and address of the author, also distinguished by the same device or motto. The essays are to be lodged at the College on or before the first day of July, 1908. No essay shall exceed 65,000 words in length, and all quotations and extracts from any published work, pamphlet, or paper, shall be by reference merely to the volume and page on which the passage desired to be quoted is to be found. The President and Council will not consider themselves bound to award the prize should any of the essays not appear to them to possess sufficient merit. Fuller particulars will be found on reference to our advertisement columns.

NEW PREPARATIONS.

SOME SPECIALITIES BY PARKE, DAVIS & CO.

MESSRS. PARKE DAVIS have sent us specimens of various new preparations which bear the impress of careful and skilful pharmacy. Amongst them are tubes containing tablets of eucaine and adrenalin for use in solution as a local anæsthetic for tooth extraction and minor operations. There is a good cathartic compound "improved" tablet coated with chocolate, which should be efficient in its action. Another useful tablet is the triple glycero-phosphate.

Formidine is a brownish powder for internal use as an antiseptic alterative, and externally as an antiseptic dusting powder. Lastly, there is also an efficient saline laxative of excellent taste and efficiency. Altogether these preparations fully maintain the reputation of the firm by which they are issued.

"WELLCOME" BRAND ANÆSTHETICS.

IT is well known that chloroform is subject to decomposition by the action of air and ordinary daylight. In order to avoid deterioration from such influences, "Wellcome" Brand Chloroform is issued in hermetically-sealed amber-coloured glass tubes. "Wellcome" Brand Ether, S.G. ·720, which conforms to the requirements of the British Pharmacopœia for pure ether, is also issued in hermetically-sealed glass tubes. By this method perfectly fresh and chemically pure anæsthetics are always available. In both cases these tubes contain accurately measured quantities, and are convenient for charging graduated drop-bottles or those employed with inhalers. Both drugs are issued in tubes of 30 c.c. and 60 c.c. They are conveniently portable, since each tube is packed separately in a wooden box, so that there is little risk of breakage by accident.

MESSRS. BURROUGHS, WELLCOME & CO. have issued under the name of "Elixoid" Pine Tar Compound, a pleasantly flavoured fluid preparation containing "Pinol" tar, terpin hydrate, Virginian prune, balsam of tolu, and ipecacuanha. This combination is said to be effective in the treatment of affection of the respiratory organs, as its active components are excreted by the lungs, thereon exerting a slow, steady and continuous action. It is stated to allay pulmonary irritation and cough, and is of special service in chronic bronchitis and bronchorrhœa in doses of half to two drachms three or four times a day. Many antiseptics in common use have undesirable properties; their application causes local irritation, whilst general toxic symptoms may follow their absorption. The new preparations by the same firm includes "Nizine," a zinc salt of sulphanilic acid, a product which is antiseptic, readily soluble in water, and produces no irritation and no toxic effects. Even in strong solution it does not coagulate albumin. Its value is stated to be great in acute gonorrhœa, and to show a marked superiority over the salts of zinc hitherto in use. Urethral and vaginal injections of solutions of strength 2 to 6 grains to the ounce are said to have proved successful, while the treatment causes no scalding, smarting pain, or inflammatory swelling. Since no coagulum of albumin is formed, the solution reaches the gonococcus in the sub-mucous tissues. A strength of one grain to the ounce is employed in gonorrhœal ophthalmia, conjunctivitis and other eye affections, when an antiseptic and sedative application is required. "Soloid" Nizin, gr. 2, affords a ready and convenient means of preparing fresh solutions for injections and for eye-lotions.

"ALAXA" is an aromatic liquid preparation of cascara sagrada prepared also by Messrs. Burroughs, Wellcome & Co. It presents in a pleasant form the tonic laxative properties of the true bark in combination with stomachic and carminative principles. It is of agreeable flavour, which certainly cannot be said of ordinary fluid preparations of cascara sagrada, which are often unpleasant. "Alaxa" is said to be suitable for use in the treatment of the constipation of pregnancy, and appears to be convenient for that purpose, as it regulates the action of the bowels without producing irritation or griping. Each fluid drachm of "Alaxa" contains the equivalent of twenty-four minims of Liquid Extract of Cascara Sagrada B.P. The dose is, therefore, one to two fluid drachms, as may be required. It is well worthy of trial by medical practitioners.

To demonstrate the Spirochæta Pallida, Messrs. Burroughs and Wellcome put up in one "Soloid" Eosin and Methylene Azur, for use in the Giemas method. The Soloid is called Eosin Azur. To prepare a solution, one Soloid should be dissolved in 5 c.c. of pure methyl alcohol. A few drops are thus run on to the film and allowed to remain one or two minutes. Then double the volume of distilled water is dropped on to the film. After another five minutes staining, the film is washed in distilled water, dried in the air, and mounted in xylol balsam. The spircchætat will be found stained a pale reddish purple, while nuclear bodies are of an intense red.

Medical Man's Claim.

AT Camelford County Court on June 20th, before his Honour Judge Granger, Dr. Ernest J. Jerome, of Camelford, claimed £42 15s. 6d. from Mrs. Eliza Wilkinson, of Portsmouth Road, Esher, for medical attendance on her brother, Captain Harry Weatherby, deceased, late of Boscastle. Mr. C. H. Peter, for plaintiff, Mr. W. M. Wivell, for defendant.—Mr. Wivell mentioned that Dr. Jerome's fees for the ten years amounted to £115 3s., £72 7s. 6d. having been paid, and £42 15s. 6d. now claimed. As there was no written guarantee, he submitted that Mrs. Wilkinson was not responsible. The family regarded the charges now made as excessive. They had offered £25 in full settlement, but this Dr. Jerome had refused to accept. Judgment for plaintiff for the full amount claimed with costs.

The Treatment of Consumption.

A DEMONSTRATION of improved methods in the treatment of consumption was given at the Brompton Hospital Sanatorium on June 21st. Noticing the relapses which the poorer consumptive patients often undergo after leaving sanatoria, Dr. Paterson tried the experiment of modifying the treatment by training patients to do work, carefully graded to their powers, and discharging them when they had become hardened and accustomed to the work they would be called upon to do on their return. The results have been very satisfactory, as of the cases transferred from the Brompton Hospital to the sanatorium last year 110 were discharged with "total arrest" of all disease, 21 as "much improved," and 25 as "improved." Another encouraging circumstance is that 113 of these ex-patients are now following their ordinary occupations.

WEEKLY SUMMARY OF MEDICAL LITERATURE, ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT SURGICAL LITERATURE.

Subcutaneous Injury to the Pancreas.—Cowen (*British Medical Journal*, May 4th, 1907) reports the case of a man, aged 38, who while walking home at night stumbled and fell over a wooden railing, hitting his abdomen as he did so. The following morning he had great pain in the stomach and back, shooting up into the chest. The pain came on in paroxysms, and was accompanied by severe vomiting. On the fourth day the pain spread all over the abdomen, and he was admitted to the Southampton Hospital. On examination the patient looked extremely ill, and was very palid. The condition was looked upon as one of peritonitis, and exploration decided on. On opening the peritoneum liquid blood began to flow from all directions. There was much clot in the pelvis. The hand passed upwards over the posterior abdominal wall came across a bulging semi-fluid swelling above the navel, and blood was seen coming through a hole in the omentum, between the stomach and the transverse colon. It became apparent that the swelling was the lesser sac filled with clot and fluid blood. The opening in the omentum was enlarged by tearing, and the clot removed by handfuls. Dark liquid blood continually welled up from the region of the pancreas, obscuring everything, so that a view of the source of flow was impossible. It was obvious that the only thing to do was to trust to gauze pressure, and accordingly twelve yards of gauze was firmly packed against the pancreas and back of the lesser sac. The abdomen was rapidly closed, the gauze being brought out of the wound on a level with the hole in the gastro-colic omentum. On the following days there was a good deal of blood-stained discharge. The gauze plug was loose and easily removed on the 5th day after operation. The wound healed up fairly well, except for a sinus where the plug had been. From this was discharged daily 6 to 8 ounces of clear fluid, which was most irritating to the skin causing a very painful dermatitis. A specimen of the fluid was examined, and it was found to be pancreatic. The patient was discharged from the hospital wearing an abdominal belt, to which is fixed a bottle and tube to catch the juice and prevent skin irritation. When last seen, six months after the accident, the sinus was still discharging 3 or 4 ounces of fluid a day, but the patient was able to do his work. S.

The Operative Treatment of Fractures.—Arbuthnot Lane (*Brit. Med. Journ.*, May 4th, 1907) describes a case of fracture of junction of the upper and middle third of the femur in which union had taken place in bad position with 3¼ inches of shortening. The seat of fracture was exposed, and the bone sawn through in two oblique planes. Before making the section it was necessary to shell off masses of bone which surrounded the seat of fracture. The soft parts were stretched and formed little obstruction to reduction when sufficient force was applied. (The author has never seen any trouble arising from such stretching of the soft parts, and does not hesitate to use a sufficient force to bring it about.) Two stout steel plates were then screwed on to the opposing fragments, so that some of the screws perforated the oblique faces, which they held securely together. They were arranged vertically, and corresponded in position to the antero-lateral and postero-lateral aspects of the shaft. Convalescene was uneventful, and the shortening was reduced to one inch, which was compensated for very comfortably by an elevation in the boot of half an inch in height. Instances of malunion of fragments of the femur in fracture through the epiphyseal line of the head are very common. The fracture is very rarely recognised at the time the injury is sustained, as the soft blunt end of the neck of the femur produces no pain when the leg is moved, so much so that the patient will often walk about in comparative comfort, being only conscious of having strained the hip-joint somewhat. The mobile head becomes displaced in the cavity, so that its convexity looks inwards, backwards, and downwards, while the stump of the neck ascends to a variable extent, retaining its contact with the anterior and upper portion of the surface of the epiphyseal line. In proportion as the neck ascends, as the ilio-femoral ligament is relaxed, the femur rotates outwards and the stump of the neck projects forwards. This outward rotation is controlled solely by the resistance offered by the anterior ligament of the hip joint. Secure union is affected by an abundant callus with great rapidity. The patient suffers from two disabilities—an excessive outward rotation of the lower limb and a limitation in flexion of the hip joint. The author has never treated a recent case, but the operative procedure of such fractures united in bad position is as follows:—The front of the capsule is exposed, and the anterior ligament cleared and defined. If the stump of the neck is excessively prominent, as is usually the case, enough is taken away from it to allow of more or less complete range of flexion. The outward rotation of the shaft is overcome by lacing up the anterior ligament transversely to the length of its fibres by silver wire, so approximating its points of attachment till the range of rotation of the limb equals that of its fellow. All the patient further requires is the compensation for a very small amount of shortening by an elevator to render his locomotion comfortable and easy. S.

A New Method of Dealing with Cleft Palate.—Starr (*Canadian Journ. of Med. and Sur.*, June, 1907) points out that (1) tension along the line of the sutures, (2) sucking of the stitches by the patient, and (3) infection from the mouth, are often the cause of non-union along the line of closure in operations for cleft palate. To overcome the first two difficulties, the author introduces a piece of aluminium, sufficiently beaten out to make it pliable, through the lateral incisions and completely surrounding the flaps. When the muco-periosteal flaps are freed, and the edges of the cleft freshened, a piece of aluminium bent at an angle where it is to fold over the outer side of one flap is passed through one lateral incision. By passing a pair of forceps into the opposite lateral incision, the aluminium can be grasped and pulled down into the mouth cavity again. It is then carried across to the point at which it entered, and the excess cut off. The aluminium can be easily perforated at one or two points with a strong needle and tied with horsehair in order to prevent the free end scraping and irritating the tongue; or the free end can be turned up into the lateral incision again, and pinched with a pair of forceps. The aluminium can be left in for eight or nine days, when it is removed by cutting it close to the lateral incision. At the same time the stitches are removed. The author reports three cases, one of which was a child, æt. 14, who had a very wide cleft which had been pronounced incurable. Beside preventing tension on and sucking at the stitches, the aluminium splint prevents adhesion taking place between the muco-periosteum and the bone of the hard palate till union of the edges has occurred. To avoid infection of the mouth, it is sprayed with a solution of boric acid and 10 per cent. rectified spirit, which easily finds its way under the splint. The opsonic index should also be taken, and if it is low to the germs within the mouth, injections of vaccines should be administered a few days before the operation.

Intestinal Obstruction due to Persistence and Anomaly of the Urachus.—Fanoni (*Med. Record*, June 1st, 1907) reports the following case: Patient, æt. 25, had for two years occasional attacks of vomiting and constipation. When seen by the author he was suffering from intestinal obstruction requiring immediate operation. On opening the abdomen a piece of intestine, so large that it looked like an over-distended stomach, was found held between the anterior abdominal wall and a stout fibrous cord the size of the little finger. This cord started at the bladder, was free in the abdominal cavity, and passed two inches to the right side of the navel to a point one inch above the latter. Here it divided into three branches, which spread out in the shape of a fan. It had no connection with the liver. On microscopic examination after double ligature and removal, this cord turned out to be the urachus, and contained a centrally located lumen. On subsequently examining the bladder by the cystoscope the left ureter opening was found in the normal position, but about four times larger than normal. The ureteral catheter passed readily to the pelvis of the kidney and there was no evidence of narrowing. The right ureteral opening was normal in size, but there was some difficulty in finding it. Two months later intestinal obstruction again occurred, and it was found that a band of adhesions had formed between the omentum and the urachal stump, and that a loop of small intestine had been gradually constricted by this adhesion. The lumen of the gut was so narrowed at both ends of the loop that lateral anastomosis was necessary, but the loop was not removed. The patient made a good recovery. On histological examination, the stump of the urachus was found to be tubercular. S.

Chylous Cyst of the Thoracic Duct.—Biggar (*Cleveland Medical Journal*, May, 1907) reports the following case: Patient, æt. 38, a healthy farmer, had been diagnosed as a case of umbilical hernia. A tumour at the umbilicus had been first noticed six months before seen by the author, and had gradually increased to the size of a cocoanut. There was no pain or impairment of bowel functions. The diagnosis of hernia and intramural abscess was eliminated on account of the change of position of the neoplasm in different postures. On abdominal exploration, a round, smooth, and symmetrical tumour, six inches in diameter, was found attached to the mesentery of the jejunum by a pedicle and having a serous peritoneal covering. The tumour was cystic in character and distinctly fluctuating. During enucleation, while stripping off the peritoneal covering, the mass was punctured, and emitted a clear, milky, white fluid. This fluid on microscopic examination proved to be pure chyle. The tumour sac was trimmed off; the pedicle ligatured with the serous sac stitched to the peritoneum as in cholecystotomy, and the abdomen closed with a tubular drain. The patient had a normal course for three days, when suddenly there developed great distension, fæcal vomiting, and rapid, feeble pulse, and collapse. The wound was rapidly opened without anæsthesia to relieve possible bowel obstruction. The entire small intestine was found to be thickened, œdematous, dark bluish in colour, but with no apparent obstruction. No treatment was of any avail and the patient died within an hour. An autopsy showed autochthonous thrombosis of the superior mesenteric vein, and the site of the tumour to be at the receptaculum chyli. The remainder of the duct was normal. S.

A Method of Reducing Old Colles' Fractures.—McWilliams (*Med. Record*, May 25th, 1907) describes the following procedure to reduce old Colles' fractures. A large engineer's monkey-wrench is procured and the blades are well padded. The patient is anæsthetised and the blades so placed on the wrist that they are entirely proximally situated to the fracture line, the edge of the dorsal blade resting against the posteriorly projecting upper edge of the lower fragment. The blades are then screwed together so as to fairly tightly embrace the tissues; with the expenditure of a very little force, a re-fracture through the old fracture line may readily be produced by twisting the wrench so as to flex the lower fragment on the upper. There is no strain whatsoever brought upon the structures of the wrist itself, which consequently remains uninjured. The damage to the tendons is trifling and is soon recovered from. The after-treatment is similar to that which obtains in cases of fresh Colles' fractures. S.

When to Operate in Acute Appendicitis.—Richardson refers (*Northumberland and Durham Journ.*, March) to the cardinal symptoms, to which, during the early stages of the disease, great attention must be paid. These symptoms are: (1) The general appearance and expression; (2) the local tenderness, with or without rigidity, in the appendix area; (3) the temperature; (4) and the pulse. So long as all these cardinal symptoms continue to improve, the inflammation of the appendix is steadily subsiding, but if any one of these symptoms has not improved, or has got worse, the inflammation of the appendix is advancing. 1. The patient may look better, the local tenderness may be less acute, the temperature may be lower, but if the pulse has increased in frequency, recommend operation. 2. The patient may look better, the tenderness may be less acute, the pulse rate the same, but if the temperature has risen recommend operation. 3. The patient may look better, the temperature may be lower—perhaps normal; the pulse may not have become more rapid, but if the local tenderness has increased recommend operation. 4. The tenderness may be less, the pulse not more rapid, the temperature lower, but if the patient looks ill recommend operation. The so-called "thready pulse" must not be looked for. This is a late sign in general peritonitis, and occurs, as a rule, in cases beyond the help of surgery. It is well to remember that in all cases of recovering abdominal lesions the pulse rate steadily falls. G.

Ligature of the Renal Vessels for the Cure of Persistent Urinary Fistula.—M. Holt records a successful case (*Lancet*, June 8th, 1907) of a patient who had suffered from traumatic rupture of his left kidney. A large abscess had been opened in the loin after the injury, this opening continued to discharge pus and urine; an X-ray photo showed that several calculi were present in the kidney; an attempt was made to remove the kidney, but this failed owing to alarming hæmorrhage. Five calculi were removed, but urine continued to discharge from the wound. Five months later a second attempt was made, but this also had to be abandoned, as the peritoneum was inadvertently opened, and it was found impossible to define the limits of the kidney tissue. Three more calculi were removed, and again hæmorrhage was very profuse. Two further attempts to remove the kidney and cure the fistula, done at intervals of some months, both ended in failure, chiefly from alarming hæmorrhage. The author having tried nephrectomy, subcapsular nephrectomy, and morcellation, and being unable to carry out fully any of these methods, decided to ligature both renal artery and vein, for while experiments on animals show that in some cases it is sufficient to tie only artery or vein to prevent any further secretion from the kidney, yet in some cases this result did not at once follow, while in every case in which both vessels were ligatured immediate atrophy of the organ followed. Both renal artery and vein were accordingly tied through an abdominal incision, with the result that in four days time all discharge of urine ceased from the sinus, the sinus itself soon healed up, now at the time the author writes two years have elapsed and the patient remains in good health, the sinus keeping firmly closed. G.

Tortion of the Testis.—H. Rigby refers to the histories of forty-nine cases (*Lancet*, May 25th, 1907) of tortion of the testis, nine of which had been treated by the author. In all cases examined the congenital abnormalities present in all cases of tortion of the cord, whether the testis had fully descended or not were:—(1) The abnormal attachment of the common mesentery and vessels to the lower pole of the body of the t and globus minor, so that the testis is attached by a narrow stalk instead of by a broad band. (2) The elongation of the globus minor. (3) A capacious condition of the tunica vaginalis. The inversion which so commonly occurs most probably takes place before the twisting of the cord, for in the author's cases, when the twist was undone after the removal of the testis, the organ was still inverted, in cases that have been untwisted at operation, nothing has been said about altering the position of the testis; in cases untwisted without operation, a simple twist from right to left or from left to right, has been made and the symptoms at once relieved. Tortion of the partly descended testis should be treated by removal of the organ as soon as possible, the tunica vaginalis should be removed with the testis and the general peritoneal cavity shut off by a ligature, the internal ring is then closed by deep sutures, to prevent the occurrence of a hernia. In the fully descended testis the conditions are different, and if the case be seen early and a diagnosis made, an effort should be made to untwist the cord. In cases of acute tortion that cannot be untwisted, the case should be treated expectantly unless very urgent, as recovery is possible without marked atrophy, and if atrophy does occur, the patient is no worse off than if the testis had been removed. In cases of recurring tortion, if the testicle is in the inguinal canal, it should be cut down upon and either removed or an attempt made to place it in the scrotum, in either case the internal ring should be firmly closed. If the testis be in the scrotum it should be exposed and fixed by the removal of the parietal layer of the tunica vaginalis, as in the radical cure for hydrocele if a patent funicular process be present, it should be closed, and the internal ring sutured to prevent the occurrence of a hernia. G.

A Case of Hydrophobia.—J. Emans (*Postgraduate* June, 1907) says the incubation period of hydrophobia is from three weeks to five years, as a rule when symptoms begin to develop there are uncomfortable sensations at the seat of the bite, which may long since have healed. The patient becomes feverish, anxious and irritable, later on there is great thirst; but with these spasms on swallowing, followed by convulsive attacks, death from asphyxia comes on in from one to four days from the commencement of the symptoms. The mortality has been reduced by the Pasteur treatment from nearly 50 per cent. to less than 1 per cent. In the author's case the symptoms commenced with twitching of the lips, which soon spread to the throat, the patient, a boy æt 17, who had received a slight bite on the finger from a dog six months before, the wound never throughout his illness showed any signs of irritation. The least draught of air seemed to bring on the facial spasms, so that the boy refused to leave his room. Later on in the night he became so wild and noisy that he had to be removed to hospital, where his case was looked on as being one of bad hysteria. His temperature was found to be 106, he became during the night more wild, snapping at the attendants, two of whom were bitten. The boy died from asphyxia at four in the morning, less than four days from the first symptom. At the autopsy the brain was intensely congested. Inoculations showed it to be a true case of hydrophobia. G.

Cysticercus of the Iris.—Gradle (*Ophthalmic Record*, January, 1907) met the above rare condition in a boy, æt. 7. The iris was much inflamed and showed at the lower part a cyst-like growth. The cyst was transparent above, but below seemed to be occupied by a yellowish body. It was crossed by bands, measured about 4 mm. in length, and showed hub-like movements. Under chloroform most of the growth was removed, the rest was absorbed completely, and the boy recovered with excellent vision M.

Primary Glaucoma and Arterio-sclerosis and Renal Impermeability. — H. Joseph (*Gaz. des Hoptaux*, July 23rd, 1904) found evidence of arterio-sclerosis in eighteen cases of primary glaucoma which he studied clinically. The manifestations of arterio-sclerosis fall into two groups: (*a*) Those affecting the cardio-vascular system; and (*b*) those affecting the renal functions. In the first group the most frequent lesions involved the aortic orifice and the peripheral arteries. Sphymographic tracings showed exaggeration of arterial tension to be notable. Renal permeability was invariably diminished. Joseph thinks that these facts appear to give to arterio-sclerosis an important part in the ætiology of glaucoma, and that high arterial tension is one of the most potent factors in the production of glaucoma.—" Abstracted for the *Ophthalmoscope* by L. Gayard. M.

MEDICAL NEWS IN BRIEF.

The Bradford Police Surgeonships—A Deadlock.

In Bradford a very peculiar situation is in existence at the present time. Some of the more forward and younger medical practitioners have taken exception to the terms of the memorandum of the Chief Constable in connection with the advertisement for a chief surgeon at £120 per annum, three divisional medical officers at £50 per annum, and four sub-divisional officers at 10s. per man per annum. The doctors took exception to the inclusive nature of the stipends offered, to the repeated manner of using the words "Chief Constable" in connection with the appointments, and to the fact that no rate per policeman attended was considered in apportioning salaries. The Watch Committee have taken the view that, seeing that casualties in the city are already paid for by voucher at the rate of 5s. in the daytime and 10s. at night, and considering the signing of a name in a book once in twenty-four hours is a light matter, that the medical men are making a serious blunder. The British Medical Association through its local branch has called in all the applications. But as the assistant to the late police surgeon, Dr. S. Lodge, is still doing the work, the Watch Committee remains master of the situation. This will go on until July 31st, unless the Medical Association issues direct instructions withdrawing this medical man from doing the work, the dead-lock will obviously fail of its purpose.

Association of Scottish Medical Diplomates.

The third annual general meeting of the Association of Scottish Medical Diplomates was held on Wednesday, June 19th, at 11, Chandos Street, London, W. The revised laws of the Association submitted by the Council were discussed and duly approved. The Treasurer reported a satisfactory balance on the year's income. The retiring President Dr. C. Farrer, was appointed honorary Vice-President. of the Association. The meeting then elected unanimously the following officers for the year 1907–1908: President, David Walsh, M.D., Hon. Treasurer, Mr. Sydney Stephenson, F.R.C.S., Hon Secretary, Arthur Harries, M.D. Two new members were elected on the Council in the persons of Dr. Skene, Perth, and Mr. Charles Ryall.

Vital Statistics.

The deaths registered last week in the eighty great towns of the United Kingdom correspond to an annual rate of 13.1 per 1,000 of their aggregate population, which is estimated at 17,978,643 persons in the middle of this year. In the preceding three weeks the rates had been 14.9, 14.5, and 13.7; Measured by last week's mortality, the highest annual death-rates per 1,000 living were:—from all causes 25.8 in Dublin, 23.1 in Belfast, 18.7 in Glasgow, 18.0 in Liverpool, 18.7 in Stockton-on-Tees, 18.8 in Wigan, 19.6 in West Bromwich, 20.0 in Tynemouth, 20.4 in Sunderland, 22.0 in Middlesbrough, and 22.3 in Preston; from measles, 2.1 in Derby, 2.2 in Walsall, 2.3 in Bolton, 2.5 in Walthamstow, 2.6 in Middlesbrough, 3.3 in Gateshead, and 3.9 in Hanley; from diphtheria, 1.3 in Leyton; from whooping-cough, 1.3 in Leyton, 1.5 in Grimsby, 1.7 in St. Helens, and 2.0 in Stockton-on-Tees; from fever, 1.0 in Stockport; and from diarrhœa, 1.1 in Oldham. No death from small-pox was registered in any part of the United Kingdom

NOTICES TO CORRESPONDENTS, &c.

☞ **Correspondents** requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Reprints.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

Original Articles or Letters intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessary for publication but as evidence of identity.

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12.

Auctor.—To answer your question would involve a great deal of historical research. The idea that plagues are visitations of Divine justice runs through most history—sacred and profane—but the rational view was taken at least as long ago as the time of Hippocrates. That great physician combated vigorously the supernatural view. In "De Libro Sacro" he declares himself opposed to the notion that some particular sicknesses were divine, or sent immediately from the Gods, and in "De Aëre, Locis, et Aquis," he likewise says that no diseases came more from the Gods than others, all coming from them, and yet all owning their proper natural causes; that the sun, cold, and winds are divine, and their changes, and influences on human bodies, are diligently to be considered by the physician. That such wise teaching should have been persistently overlooked must be attributed, we fear, to the superstitious self-interest of those who ought to keep men's minds in subjection.

Tablet.—Yes, there is no doubt that lead can be conveyed in ice-creams, though we do not remember having come across any specific instance in this country. Dr. Alessandro Baldoni, of Rome, has lately discovered an appreciable proportion of lead, on an average 0.69 milligrammes per 228 gramme of icecream. The samples were purchased from street vendors. He attributes the lead to alloy used in making the mixing vessels. The article on the subject will be found in the *Riforma Medica.*

Dr. P. R.—The origin of these things cannot be traced with satisfaction or certainty. There is a good deal to be said for Mr. George Bodington, surgeon, of Sutton Coldfield, being called the "Father of Open-air Treatment." His pamphlet—"An Essay on the Treatment and Cure of Pulmonary Consumption (on principles natural, rational, and successful), with suggestions for an improved plan of treatment of the disease amongst the lower classes of society; and a relation of several successful cases restored from the last stage of consumption to a good state of health"—is very rare. There is one copy in the library of the Birmingham Medical Institute.

Bane.—The hedgehog can eat without discomfort as much opium as a Chinaman can smoke in a fortnight, and can wash the meal down with as much prussic acid as would kill a regiment of soldiers. It is capable of swallowing arsenic with just as much relish as it eats cockroaches. It is quite immune to the venom of the snake.

Meetings of the Societies, Lectures, &c.

Wednesday, June 26th.

Society of Tropical Medicine and Hygiene (20 Hanover Square, W.).—8,30 p.m.: Address: The President (Sir Patrick Manson). Lantern Demonstration: Dr. Daniels.

Medical Graduates' College and Polyclinic (22 Chenies Street, W.C.).—4 p.m.: Mr. T. P. Legg: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Mr. A. H. Tubby: Surgical Diseases of Children.

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—Cliniques:—2.30 p.m.: Skin (Dr. Meachen), Eye (Mr. Brooks), Medical Out-patient (Dr. Whipham).

Thursday, June 27th.

Royal College of Physicians of London (Pall Mall East).—5 p.m.: Croonian Lecture:—Dr. W. J. R. Simpson: Plague.

Medical Graduates' College and Polyclinic (22 Chenies Street, W.C.).—4 p.m.: Mr. Hutchinson: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Mr. J. Berry: The Treatment of Hip Disease.

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Gynæcological Operations (Dr. Giles). Cliniques:—Medical Out-patient (Dr. Whiting). Surgical Out-patient (Mr. Carson). 3 p.m.: Medical In-patient (Dr. Chappel). 4.30 p.m.: Special Demonstration of Medical Cases (Dr. Auld).

Hospital for Sick Children (Great Ormond Street, London).—4 p.m.: Lecture:—Dr. Garrod: Diabetes in Children.

Friday, June 28th.

Medical Graduates' College and Polyclinic (22 Chenies Street, W.C.).—4 p.m.: Dr. D. Grant: Clinique. (Ear.)

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—9.30 a.m.: Clinique:—Surgical Out-patient (Mr. H. Evans). 2.30 p.m.: Surgical Operations (Mr. Edmunds). Cliniques:—Medical Out-patient (Dr. Auld), Eye (Mr. Brooks). 3 p.m.: Medical In-patient (Dr. Leslie).

National Hospital for the Paralysed and Epileptic (Queen Square, Bloomsbury).—3.30 p.m.: Clinical Lecture:—Dr. F. Buzzar: Acute Poliomyelitis.

Central London Throat and Ear Hospital (Gray's Inn Road, W.C.).—3.45 p.m.: Demonstration: Dr. Abercrombie: Nose and Accessory Sinuses.

Vacancies.

London County Asylum, Claybury.—Junior Assistant Medical Officer. Salary, £150 per annum. Applications to H. F. Keene, Clerk of the Asylums Committee. (See advt.)

Newcastle-on-Tyne, Dispensary.—Visiting Medical Assistant. Must be doubly qualified and registered, and be prepared to remain at least one year. Salary £160 for the first year, and £180 afterwards. Applications to the Honorary Secretary.

Egypt.—Sub-Inspector of Ophthalmic Hospitals. Salary £500 a year, with two months' salary in lieu of travelling expenses to and from England. The appointment is for two years, during which three months' leave on full pay will be allowed. Applications will be received in London up to July 7th by A. F. MacCallan, Esq., 32 Bedford Gardens, Kensington, W.

Stockport Union.—Resident Assistant Medical Officer. Salary commencing at £130 per annum, with furnished apartments, rations, etc. Applications to Charles F. Johnson, Clerk to the Guardians.

Corporation of Sheffield.—Junior Assistant Medical Officer to the Fever Hospitals. Salary £130 per annum, with board, lodging, and washing. Applications to H. Sayer, Town Clerk, Sheffield.

Leeds Union.—Assistant Medical Officer. Salary £100 per annum, with board, washing, apartments, and attendance. Particulars of the Medical Superintendent at the Union Infirmary, Beckett Street.

Edmonton Union.—Assistant Medical Officer at the Workhouse, Upper Edmonton. Salary £180 per annum. Application forms of F. Shelton, Clerk, White Hart Lane, Tottenham.

Tunbridge Wells General Hospital.—House Surgeon. Immediate applications to the Secretary, at the General Hospital.

Carmarthenshire Infirmary.—Resident Medical Officer. Salary £100 per annum, with furnished apartments, board, attendance, etc. Applications to Howell Howell, Secretary.

Appointments.

Drury, G. H., M.B., M.S. Ed., Medical Officer and Public Vaccinator for the Fifth District of the Wells (Somerset) Union.

Fanning, J. J., L.R.C.P. and S. Edin., L.F.P.S. Glasg., Certifying Surgeon for the Birr District of King's County.

Geddie, David Watson, M.A., M.B., C.M. Aberd., Anæsthetist to the Royal Sick Children's Hospital, Aberdeen.

Lyon, T. M. M., M.D. Edin., Certifying Surgeon under the Factory and Workshop Act for the Mid-Calder District of Edinburgh.

Peddie, C., L.R.C.P. and S. Edin., L.F.P.S. Glasg., Certifying Surgeon for the Withnell District of the county of Lancaster.

Porteous, Herbert Llewellyn, L.R.C.P. Lond., M.R.C.S., District Medical Officer of the Stroud Union, Gloucester.

Richards, John, M.B., F.R.C.S. Edin., Medical Superintendent of the Joint Counties Asylum, Carmarthen.

Spaight, Henry William, L.R.C.P., L.R.C.S., L.M. Irel., District Medical Officer for the Helston Union, Cornwall.

Willcox, W. H., M.D. Lond. M.R.C.P. Lond., Physician to Outpatients at St. Mary's Hospital, Paddington.

Births.

Eager.—On June 18th, at "Abingdon," Durban Road, Watford, the wife of Mervyn Eager, M.R.C.S.Eng., of a daughter.

Gunning.—On June 13th, at 7 St. Michael's Road, Bedford, the wife of Lieut.-Col. R. C. Gunning, R.A.M.C. (retired), of a son.

Howkins.—On June 18th, at Milverton, Yardley, Worcestershire, the wife of Cyril Howkins, M.R.C.S., L.D.S., of a daughter.

Nimmo.—On June 20th, at 119 King's Terrace, Southsea, the wife of Staff Surgeon Frank H. Nimmo, R.N., H.M.S. Essex, of a daughter.

Marriages.

Bent—Ransom.—On June 19th, at St. Mary's Church, Balham, Sidney C. H. Bent, M.D.(Brux), M.R.C.S., L.R.C.P.(Lond.), third son of the late John F. V. Bent, M.D., to Ellen Muriel, only daughter of the late Thomas R. Ransom and Mrs. Ransom, Upper Tooting.

Bliss—Chitty.—On June 19th, at All Saints' Church, Highgate, Norman Cleaver, third son of Edwin Bliss, of Highgate, to Edith Goldney, elder daughter of A. Goldney Chitty, M.R.C.S., L.R.C.P., of Highgate.

Gillespie—Fynn.—On June 19th, at St. Mark's Church, Southampton, Thomas Gillespie, M.B., B.C. (Cantab.), second son of Thomas Gillespie, J.P., of Morpeth, Northumberland, to Josephine Eva, second daughter of Arthur F Fynn, of Bassett, Hampshire.

Smith—Greenwell.—On June 15th, at All Saints' Church, Gosforth, Newcastle-on-Tyne, Charles W. Smith, M.B.Lond., of Hillsborough, Sheffield, to Ruby, third daughter of the late Rev. Wm. Greenwell, M.A., late Vicar of Horton, Northumberland.

Deaths.

Lacey.—On June 8th, at Rangoon, of heart failure, William W. Lacey, M.R.C.S., L.R.C.P., of Castlepark House, Exmouth, aged 44.

Wilson.—On June 22nd, at Laxfield, Suffolk, in her 88th year, Caroline, widow of Robert R. Carley, M.R.C.S., of Laxfield.

IRISH POOR-LAW AND LUNACY INTELLIGENCE,

Being the Weekly Supplement of the "Medical Press and Circular."

WEDNESDAY, MARCH 13TH, 1907.

Notice to Correspondents.

Poor Law Medical Officers and other subscribers to The Medical Press and Circular are invited to make use of the facilities provided by the Management of the Journal for obtaining information on all matters connected with the Poor-Law Medical Service or the Medical Profession generally in Ireland.

The Editor will be glad at all times to receive letters or marked copies of newspapers dealing with matters of medical interest. All communications must be addressed to the Office of the Journal 18 Nassau-street, Dublin, and should be delivered not later than Saturday morning to ensure attention in the issue of the following week.

EVENTS OF THE WEEK.

The cost of the *Journal of the Irish Medical Association* has exercised the minds of the more thoughtful of the members and attracted the attention of the Council; its abolition as useless has been discussed; but the number for March suggests the possibility that its existence may be a grave danger to the Association. In the February number the following resolution of the South Tipperary branch was published;—"That the dispute in connection with the engagement of an assistant at surgical operations in the Clogheen Workhouse Hospital should be referred to the Council of the Irish Medical Association." At the meeting of the Council on January 31st, on the motion of Dr. Hennessy, this resolution was discussed and adjudicated on. The Association is empowered to arbitrate in disputes between individual members of the profession *when such arbitration may be requested;* and by a by-law of 11th November, 1902, the Council is authorised to appoint one or more arbitrators either from their own body or from among the members of the Association, or otherwise, for the settlement of professional difficulties and disputes in which any member desiring assistance may be concerned. No arbitration can take place unless both contending parties agree to it, and to submit to the decision of the arbitrators. In the present case only one of the parties demanded the interference of the Council, the others refused to accept it, and therefore the Council had no right to discuss and decide the case at all. The Honorary Secretary of the Association is supposed to know the power of the Council and the rules and regulations of the Association; and it was obviously his duty to advise the Council that it was acting *ultra vires*. Whether, as he states, in his capacity of editor of the *Journal*, "it is well, however, when such disputes do arise that there should be such a tribunal as the Council to refer them to." is a matter of opinion—not of fact; if such cases, with all their details and with the editor's comments, are to be published and disseminated broadcast in the *Journal*, then we think it would be anything but well that there should be such a tribunal established. The *Journal* instead will become a dangerous and disruptive force if the proceedings of the Council in arbitration cases and the letters written by the contending parties are to be published. The object of arbitration in professional disputes is to put an end to disagreements and to restore harmony, not to spread abroad throughout the Association, and far beyond it, the details of quarrels, and the winged words men may write or utter in the heat of the contest. That does not tend to peace and renewal of friendship. Nor can there be any excuse for the amazing indiscretion of the editor's utterances in his notes on the Council meeting. Whatever his own personal opinion may be, he has no right, as editor of the *Journal* of the Association, to take a particular view or adopt praise or censure. Very properly the chairman ruled at the meeting, "I cannot allow personalities to be discussed. We must only consider the principle." Yet in the face of that ruling the editor of the *Journal* writes an article mainly personal, and certainly likely to be most damaging to the Association.

The deaths registered in the Dublin area for the week ending 2nd inst. represented an annual death rate of 30.4 per 1,000 of the population. The rates in other capital cities, according to the latest returns, are:—London, 18.4; Edinburgh, 17.4; Calcutta, 39.1: Paris, 31.2; Brussels, 21.1; Amsterdam, 21.4; Copenhagen, 18.9; Stockholm, 13.3; Christiania, 20.8; St. Petersburg, 30.9; Berlin, 16.4; Vienna, 21.2; Rome, 25.7. Beside Dublin the following cities in the Registrar-General's list present rates exceeding 20:—Glasgow, 22; Calcutta, 39.1; Bombay, 39.3; Madras, 38.2; Paris, 31.2; Brussels, 21.1; Amsterdam, 21.4; Christiania, 20.8; St. Petersburg, 30.9; Morocco, 33.1; Breslau, 24.1; Vienna, 21.2; Buda-Pesth, 24.1; Prague, 23; Trieste, 34.6; Rome, 25.7; Venice, 24.3; Boston, 22.6. The following towns in Ireland present for the month ending 2nd inst. rates of 20 or over per annum per 1,000:—Armagh, 30.9; Ballymena, 31.1; Belfast, 26.3; Clonmel, 26.9; Cork, 25.2; Drogheda, 25.6; Dundalk, 27.9; Galway, 25.3; Kilkenny, 27; Limerick, 20.9; Lurgan, 29.9; Newry, 20; Newtownards, 21.5; Portadown, 22; Sligo, 20.4; Tralee, 31.7; Waterford, 35.1; Wexford, 36.2.

The Belfast Health Commission began its sittings on the 5th inst. Among the witnesses examined have been the Registrar-General, the Chief Clerk to the Corporation, the Chairman of the Public Health Committee (Dr. King-Kerr), the Medical Officer of Health (Dr. Bailie).

The Kerry County Council have unanimously resolved to join with the counties of Limerick and Clare for the purpose of establishing a sanatorium for consumptives.

Some alarm was raised in the neighbourhood of Charleville a few weeks ago by the deaths of two patients in whose cases some of the symptoms of cerebro-spinal fever were present. That matter has been inquired into by Dr. Brown, Local Government Board Inspector, and he agrees with the medical men in attendance, Drs. Cremin and Connery, in thinking that the disease was not cerebro-spinal fever in either case.

At the meeting of the Galway Board of Guardians on the 27th ultimo Dr. O'Brien was elected medical officer of the Aran Dispensary District, by a large majority. Dr. Cusack, the other candidate, is a young man with the record of a distinguished career at the Queen's College, Galway. We congratulate him on his escape from having his professional life ruined by exile and isolation in these remote islands.

Whilst Dr. Wilson, Medical Officer of the Enniskillen Workhouse, was on holidays he was called in by his substitute, Dr. Betty, to assist at two operations in the infirmary. For these services, Dr. Wilson sent in a claim for two guineas, which the Guardians declined to pay until directed by the Local Government Board. This Board have now written to say that they did not consider the medical officer entitled to receive any extra remuneration under the circumstances. If this contention be well founded, we might, in all seriousness, ask the question :—"When is a holiday not a holiday ?" We think, however, that the Local Government Board is quite wrong in this decision. While on leave, the Guardians had no claim on the services of Dr. Wilson, and when they called on him, through their agent, Dr. Betty, they are responsible for his fee. We hope that the Irish Medical Association will take the matter up on behalf of Dr .Wilson.

The Clogher Board of Guardians have requested the Local Government Board to hold a sworn inquiry in connection with the medical treatment of Edward Boyle, William Parson, and George Giles, all of whom have been treated in the workhouse. It was in relation to the treatment of Boyle that the cause of action for libel arose which Dr. Ross is taking against a guardian named Donnelly. Both litigants express themselves satisfied with the action of the Guardians, and Dr. Ross is most anxious that the inquiry should be held.

Dr. Browne, Dispensary Medical Officer, Ballynahinch, in the Downpatrick Union, having been certified unfit for duty by Dr. Tate, owing to an attack of influenza, the relieving officer reported that he had been obliged to retain the services of Dr. Hamilton, who refused to act for less than £1 1s. per diem. The Guardians scale only allows £3 3s per week, but Dr. Hamilton resolutely refused to accept this. Some members of the board suggested that they should get a doctor from Belfast, but it was feared that they could not get one to come for less than a guinea ; so that they ultimately decided to leave the matter in the hands of the relieving officer, as they admitted that the doctors had them in a fix.

Dr. L. Kidd, Enniskillen, has written to the Irvinestown Guardians with reference to his fee of £5 5s., for performing a difficult operation in the infirmary, respectfully declining to modify his charge. It was not until after due consideration, and in order to save correspondence and trouble, that he asked for the very moderate fee of £5 5s., a sum substantially less than he would be justified in claiming. He pointed out that it was not for assisting at, but for performing a surgical operation, that he charged the fee It was decided to pay the amount, subject to the sanction of the Local Government Board.

Dr. R. T. Hayes has been elected Medical Officer of Balrothery Workhouse.

Dr. Corcoran has been elected medical officer of the Ballinrobe District. There were two other candidates. The election took place amid wild disorder, and the board had to adjourn for half an hour to allow the boardroom to be cleared.

We regret to note the death of Dr. John Nolan, who had been resident medical officer of the Limerick Workhouse for over twenty years.

CASTLEREA UNION.

The medical officers of the Castlerea Union have again applied to the Guardians asking for the adoption of a graded scale of salaries. The following passage occurs in their letter to the board :—

"Under recent Acts of Parliament and late rules and regulations of the Local Government Board, increased particularity in performance of duties, and largely added new duties, with still inadequate or no remuneration, have been placed on the shoulders of the unfortunate Poor Law Medical Officers. Notwithstanding all this, at present your medical officers receive in wages a lesser sum than they received thirty-five years ago, and further, to-day you enjoy the services of two medical officers at a lesser salary than you paid one medical officer twenty-five years ago for the joint appointment. You, yourselves, know that this is not just ; that it is cruel and ungenerous in the face of the acknowledged increase in the necessary expense of present day living, and of labour generally. You would not dream of getting a labourer to work now for the wages he received thirty or forty years ago ; neither would you get the domestic servant, the mechanic, the architect, the engineer, yet it is reserved for the unfortunate medical officer, who is the sole dependence of the general community in their corporal afflictions, and who is ever, in the interest and for the protection of the public, at danger's post, in endemics and epidemics, no matter how virulent and dangerous to his own and to his family's lives, to work for wage that neither affords the means of living or of efficiently discharging his important and onerous duties.

Gentlemen, you pay, *in toto*, in salaries to your medical staff, £510 per annum. Half of this is recouped from Government Consolidated Fund, and more than a fourth is recouped under the Equivalent Grant, so that the rates of the entire Union is responsible for something like £100 to the entire salaries."

The communication was marked "received," Mr. Patrick Webb, interjecting, "throw it in the waste paper basket."

IRISH WORKHOUSE ASSOCIATION.

The annual general meeting of the Irish Workhouse Association was held last week in the Mansion House. Mr. Charles Eason presided.

Speeches were delivered by the Chairman, Mrs. Haslam, Miss Armstrong, Rev. Father Finlay, Mrs. Foran, Mr. Hugh Law, M.P. ; Miss Rose Barrett, Dr. M'Walter, Mr. A. W. Samuels, Miss Welply, and Rev. J. D. Osborne.

The following resolutions, among others, were adopted :—

"That this meeting begs respectfully to urge on the Government to take the Report of the Viceregal Commission on Poor Law Reform into their immediate consideration, with a view to prompt action to carry out its recommendations."

"That this meeting urges on all members of the Irish Workhouse Association to take every opportunity, public and private, of directing attention to the Report, and that it be an instruction to the Executive Committee to promote the discussion of the Report at Conferences of Poor Law reformers and representatives of the public bodies concerned."

"That this Association thinks that in any legislation carrying out the recommendations of the Commission provision should be made to secure the continued and adequate representation of women on Boards of Guardians."

Mrs. Rushton said she had been requested by Lady Aberdeen to announce that a meeting of the Women's National Health Association of Ireland would be held at the Royal College of Physicians on Wednesday, the 13th inst.

FEVER IN ARDNAREE.

At a recent meeting of the Ballina District Council, a circular letter from the Local Government Board was read calling attention to the prevailing outbreak of cerebro-spinal fever, and the urgent necessity for sanitary precautions being taken.

Notwithstanding outbreaks of typhus, diphtheria, and febrile diseases, the following extract from their discussion on the circular shows how completely callous the members are:—

Mr. Muffney—The sanitary officers will bother their heads very much about it. Some four or five years ago we had several applications to put in new sewerage for Ardnaree, as there was an immense number of houses without water closets or connections; and since that sewerage was carried out at considerable expense never a single water closet was erected.

Mr. Joynt—There was one.

At a subsequent meeting, reporting on a case of fever in Ardnaree, Dr. Macaulay attributed the outbreak to insanitary surroundings and shortage of water.

Mr. Muffney—We made a new sewer there, and there never was a connection made to any house.

Mr. Walsh—Bring the law of compulsion to bear on them. It speaks very badly for the town to see an outbreak of fever in it at this time of year. Every man in Ardnaree should be compelled to get a *water closet irrespective of politics.*

Mr. Chambers—Ah, there is no politics in water closets.

Mr. Walsh—Well, if there is not there is some favouritism in regard to the matter.

It is not to be wondered at that under these circumstances fever should be prevalent in Ballina.

A CLARE MAGISTRATE ON MEDICAL FEES.

The usual weekly meeting of the Ennistymon board of guardians was held on Tuesday, 5th inst., at which Mr. M. Leyden, J.P., presided.

A resolution was adopted at the previous meeting requesting the local magistrates, in the committal of lunatics to the asylum, not to certify for more than one guinea to medical officers for the examination of lunatics, and Mr. H. B. Harris, to whom a copy of the resolution was sent, replied that he never signed a certificate in lunacy cases for more than 21s., because he considered it the easiest-earned money a doctor received, and because, also, he considered it would be an abuse of a magistrate's privilege to give more, unless under very extraordinary and exceptional circumstances. He wished they could control the medical profession so as to compel all medical men to accept, in town and country, a fee of 2s. 6d. for a visit to a doctor's own house, 5s. for a visit of two miles distance, and 10s. for a distance under five miles. As to operations, their charges were exorbitant and should be reduced, in cases where the patients were not wealthy and very well off. The State should give a contribution towards operation fees in certain cases, because very useful lives were lost owing to humble persons not being able to pay the fees insisted upon, and in other cases people even delaying calling in a doctor owing to the excessive fees, until it was too late.

Mr. H. B. Harris is evidently a "very harbitrary gent."

EVENTS OF THE WEEK.

THE deaths registered in the Dublin area in the week ending 23rd ult. represented an annual death-rate of 27.9 per 1,000 of the population. The rates in other capital cities, according to the latest returns are:—London, 17.1; Edinburgh, 18; Calcutta, 35.8; Paris, 26.6; Brussels, 18.6; Amsterdam, 20.4; Copenhagen, 16.9; Stockholm, 15.5; Christiania, 18.7; St. Petersburgh, 31; Berlin, 16.4; Vienna, 19.3; Rome, 24.1. The following cities in the Registrar-General's list, besides Dublin, have rates exceeding 20:—Glasgow, 20.3; Calcutta, 35.8; Bombay, 33.5; Madras, 34.5; Paris, 26.6; Amsterdam, 20.4; St. Petersburg, 31; Moscow, 32; Breslau, 23.7; Buda-Pesth, 23.9; Trieste, 34.6; Rome, 24.1; Venice, 23.4; Philadelphia, 22.4; Boston, 20.7. The following towns in Ireland present, for the month ending 23rd ult., annual rates exceeding 20:—Armagh, 29.2; Ballymena, 26.3; Belfast, 24.3; Clonmel, 25.6; Cork, 25.7; Drogheda, 26.6; Dundalk, 27.9; Galway, 20.4; Kilkenny, 33.2; Lurgan, 31; Newry, 21; Newtownards, 22.9; Portadown, 20.7; Tralee, 22.5; Waterford, 34.6; Wexford, 32.7.

The total number of notified cases of cerebro-spinal fever in Belfast at time of going to press has been 118, with 70 deaths. The Lisburn Guardians, in view of the spread of the epidemic, have ordered the schools in Dunmurry, which are contiguous to the city boundaries, to be disinfected. They further agreed to have the tramps disinfected on admission to the workhouse, in presence of the Medical Officer. Dr. MacKenzie respectfully declined to inspect such operations, as it did not come within his duties, without extra remuneration, and it was arranged that the Clerk wire to the Local Government Board to ascertain what was the Medical Officer's duty in a case of this kind. We should strongly advise Dr. Mackenzie to have nothing to do with forcible disinfection of tramps, or anybody else, or he may find himself let in for an action for assault. Guardians have no power to disinfect anyone.

In a letter to the *Freeman's Journal* of 27th ult., Dr. M'Walter defends the Dublin Corporation against charges of carelessness with regard to the health of the city. He says—"It is well known that the Dublin death-rate is high because of the large infant mortality." This is a mistake. The high death-rate is principally due to tuberculosis and diseases of the respiratory tract. As a matter of fact Dublin contrasts not unfavourably, as regards infant mortality, with many other towns in the Kingdom.

The Lisburn Board of Guardians had under consideration, at a recent meeting, the advisability of appointing a midwife for the district of Ballylesson, in support of which a deputation of ladies had appeared before the Board a fortnight previously. The appointment had been recommended by Dr. Clibborn, the Local Government Board Inspector; but, before making it, the Guardians requested the opinion of the Medical Officer of the district, Dr. Gavin Orr. This gentleman accordingly wrote to the Board, but gave such a lukewarm opinion in favour of the appointment that the Guardians considered themselves justified in refusing to saddle the ratepayers with any increased expenditure. The district comprises 11,961 acres, with a population of 4,296, in 1901, and there are about 84 births annually. We should imagine that the services of a skilled midwife would be found most useful; nay more, would be absolutely necessary, in such a district, and we cannot appreciate the considerations which prevent a medical officer from expressing his opinion firmly in favour of the appointment. We hope the time is not far distant when every dispensary district in Ireland will be provided with a fully-trained midwfe, so that every lying-in woman may have the attention and skill necessary to carry her through her hour of trial to perfect recovery.

The Irvinestown Guardians spent a considerable time discussing an application from Dr. L. Kidd for a fee of £5 5s. for performing an operation in the infirmary. They ultimately passed a resolution asking Dr. Kidd to be satisfied with a smaller fee. Some of the Guardians, as well as the Clerk, semed to think that the scale of fees drawn up under the Dispensary Regulations, should also apply to fees for operations in the infirmary, and consultations with the workhouse doctor. This, however, is not the case, and the Medical officer of a Workhouse has full liberty to call in whomsoever he will to assist him.

The Belfast Guardians have come to the conclusion that there is no necessity for two fever hospitals in the union, and have directed the medical officers to send all cases of infectious disease to Purdysburn. The average weekly number at present in the workhouse fever hospital reaches almost 100, including, during the past week, two cases of cerebro-spinal fever. It will be interesting to watch the result of this procedure.

The following officers of the Leinster Branch of the British Medical Association have been elected for the ensuing year:—President—John Lentaigne, F.R.C.S. President-Elect—J. Wallace Boyce, M.B. Vice-Presidents—F. W. Kidd, M.D., Sir William Smyly, M.D. County Representative of Branch on Irish Committee—J. M. Kenny, M.B., Granard. Hon. Secretary and Treasurer—Professor White, Royal College of Surgeons, Dublin.

Mr. Birrell last week received in private Sir Arthur Chance and Dr. Donnelly, who attended as a deputation from the Irish Medical Association to complain of limitations recently placed by the Irish Local Government Board upon the mode of selecting candidates for medical Poor Law appointments, especially with reference to their vaccination qualifications. Mr. Birrell promised to consider the points brought before him.

We quote below extracts from a highly interesting report on the increase of insanity in the County Wexford, presented by Dr. Thomas Drapes to the Committee of the Enniscorthy District Asylum. Dr. Drapes places most stress on defective education and alcoholism as causes of insanity, whereas he considers tea-drinking of little importance.

IRISH POOR LAW REFORM.

The annual meeting of the Leinster branch of the British Medical Association was held in the Royal College of Physicians, Dublin, last week, Surgeon Lentaigne, President, occupied the chair.

The President, in delivering his address, devoted himself to the report of the Viceregal Commission on Poor Law Reform in Ireland, and expressed his concurrence with the majority of the recommendations set forth in it. What mostly concerned medical men was the re-organisation of the county and workhouse hospitals, the very valuable suggestions as to the treatment of the sick, and especially of tuberculosis, the proposed regulations for the accommodation of the insane, of epileptics, and of the aged and infirm, and the formation of what had been rather unfortunately called a State Medical Service. The latter designation was a bad one, and the service should be called national or civil. With regard to the reorganisation of hospitals, a much-needed reform was proposed. All county and workhouse hospitals were to be brought into a county hospital system with the county infirmary as the central institution. At least a minimum standard of efficiency was to be secured by inspection. The recommendations in the report for the accommodation and treatment of patients suffering from tuberculosis were most valuable. It was important that some system of arranging for the suitable employment of the convalescent cases should be introduced. In conclusion, Dr. Lentaigne said that of all the recommendations in the report the best and most important, from their point of view, was that for a State, or as it should be called, a National Medical Service. That scheme was, he believed, the keystone on which the entire fabric of reform depended.

On the motion of Dr. Conolly Norman a resolution was adopted congratulating the members of the Viceregal Commission on their excellent report, and expressing approval of the suggestion that the entire Medical Poor Law Service should be formed into a National Service; and the opinion that the Imperial Treasury should provide the funds necessary for the payment of the members of the service, that the service should be entered by competitive examination, and that the members of the National Service should have a voice in selecting a due proportion of the members of the Central Board of Control.

INCREASE OF INSANITY IN CO. WEXFORD.

Dr. Thomas Drapes, M.B., R.M.S., of Enniscorthy District Asylum, has issued a special report dealing with the increase of insanity in County Wexford during the decade ending 1903. Discussing causes and conditions, he says:—"Insanity in those who work their brains hardest—such as statesmen, eminent professional men, and others, who have to endure a high degree of mental strain—is comparatively rare. The rural and uneducated class contribute the highest quota. In the matter of education the County Wexford compares unfavourably with the rest of Ireland generally, and still more markedly with the other counties of the same province. Wexford has a ratio of insane to population considerably higher than the average for all Ireland, and without wishing to dogmatise on the subject, I am inclined to think that there may be some connection between the two facts revealed by the Census returns. Undoubtedly, better education would, at any rate, tend in the long run to develop a higher standard of mental stability, and, probably, *pari passu*, a robuster constitution in the structure of the brain, which would thus be less liable to break down under strain.

The cases in which drink was an assignable cause, primary or contributory, increased from 121 in the first decade to 213 in the last; a rise of 76 per cent. They formed 16 per cent. of admissions in the earlier period, and 23.6 per cent. in the second; an increase of 47.5 per cent. This is not to be wondered at, when we take into consideration the enormous amount of money spent on drink, which, in the County Wexford alone, amounts to £400,000 per annum, and to the unscrupulous action of the licensing authorities in the reckless and indiscriminate multiplication of publichouses with the connivance of the State, thus increasing largely the facilities for the formation of drinking habits among the population, an evil which is bringing about deplorable results.

Tea drinking has been regarded by some as a predisposing, if not a directly exciting cause of insanity, but to my mind this view is based on wholly insufficient grounds."

LIMAVADY UNION.

At a recent meeting of the Limavady Guardians the Clerk said he had written to Dr. Lane, Medical Officer of the Bellarena Dispensary District, informing him that at the last meeting of the board Miss Martin had alleged that he had unduly delayed visiting a child who had died in the fever hospital on the 8th from diphtheria. Miss Martin had stated that a medical relief ticket had been left at his residence on the 5th, and that he did not attend to the child till the following day. He had received a letter from Dr. Lane offering an explanation on the matter. The doctor stated that on Tuesday, the 5th, he left home at 6.40 a.m. to visit a patient at Benone. On returning he was taken to Bellarena to see a second case, and from there proceeded to his dispensary. He reached home about 6.20 p.m., and then he found a ticket issued by Mrs. Gibson, Broighter, which had been left during his absence. No message was left as to the nature of the illness or otherwise, and the messenger was informed the hour he left home, where he was and the probable time of his return, and had the case been an urgent one the messenger could easily have taken the ticket to the dispensary, or else intercepted him on his return home. He (the doctor) entered the ticket on his list for the following morning. He went out that night again about 7.45 p.m., and returned at 10 p.m., and during his absence an uncle of the boy's called to inquire if the ticket had been left. The uncle then stated that the boy was suffering from a sore throat, and left a message asking him to call that night or early the following day. He attended the case the first thing next morning. The doctor further said he would like to add that the case was not urgent when he saw it, and it was the seventh day of illness.

The Chairman—I think the doctor's explanation is fairly satisfactory.

Miss Martin—I do not think so. The doctor should have gone the first night.

Mr. Guthrie—I think if there was any carelessness it was on the part of those who left the ticket.

Mr. O'Loane said if the case was urgent the ticket should have been marked so.

The Guardians decided to accept the doctor's explanation as satisfactory.

UNION MEDICAL CONTRACTS.

The Local Government Board have written to the various Boards of Guardians with regard to the taking of tenders for medicines and medical and surgical appliances for the following year.

The Board drew attention to Article 10 which is as follows:—"Recoupment from the Local Government Taxation (Ireland) Act, will not be allowed in any case where the Guardians accept a tender other than the lowest tender received by them for the supply of drugs or other articles contained in the prescribed lists, unless the Local Government Board, on application being made to them for that purpose, approve of the acceptance of the tender." The Board also expressed the wish to be understood that recoupment cannot be allowed in any case where the Guardians have accepted a tender other than the lowest, unless it can be clearly shown to the satisfaction of the Board that there are good and sufficient reasons for acting otherwise. They would not, of course, expect the Guardians to accept the lowest tender where the party tendering had previously proved unsatisfactory in any Union in Ireland, nor where the balance of convenience and speedy delivery was in favour of a firm whose tender was slightly above the lowest tender. In any case where it is considered that convenience and promptness of delivery justify the Guardians accepting a tender other than the lowest, detailed evidence on the point will be expected by the Board.

The reference to "convenience and promptness of delivery" seems to suggest that the Local Government Board will not this year raise objection to a preference being given to Irish firms.

BALLINASLOE DISTRICT ASYLUM.

At the monthly meeting of the Committee, Dr. Kirwan, Resident Medical Superintendent of the Asylum, reported that the health of the Asylum for the last month had not been so good. There had been several fresh cases of enteric fever and influenza, and two deaths had occurred from enteric. The sewerage was bad, and he was having several alterations made.

The Aughrim Hurling Club wrote recommending Mr. P. Carey for the position of an Asylum Attendant.

Mr. P. J. Kelly said they would not be dictated to.

Dr. Kirwan stated the application would come up at next Committee meeting, so the mattter was dropped.

The connection between hurling and lunacy, and how a hurling club is in a position to judge of the fitness of a member to take charge of the insane, is not very clear. Possibly, the members of the Aughrim Club desire to have a friend in court in cases of cracked heads.

SLIGO DISTRICT ASYLUM.

At the monthly meeting of the Committee, the Resident Medical Superintendent submitted a statement relative to chronic harmless lunatics. There are at present in the asylum 73 chronic harmless lunatics who are capable of doing some work. Out of the 73 only 12 are under 40 years of age. With regard to the question of such patients being taken out by their friends, it must be borne in mind that because patients are quiet and do some work in the asylum, it by no means follows that they therefore will remain quiet and contnue to work if taken out of the asylum. Out of the 73 patients referred to 20 have been discharged at one time or another—13 once, 5 twice, and 2 three times. It must also be borne in mind that many persons who become insane develop a dislike to some of their immediate relatives—*i.e.* those with whom they have been living. To discharge patients in care of such relatives would be only to provoke a relapse. In regard to the particular case referred to by Father Flynn, I have not included him in the return. He has been an inmate for over ten years. He labours under the delusion that someone sucks his blood at night; sometimes he accuses an inmate, and at other times an attendant.

The Chairman said he knew of a case where one of the inmates went into the yard and cut a pound of steak off a live cow's leg, and then cooked it.

Rev. Mr. Flynn—The Chairman's barbacue.

The Committee made a minute that they would consider applications at the next meeting of the Board from respectable farmers and others who are desirous of employing or hiring out discharged patients as farm labourers, wages offered to such labourers to be approved of by the committee.

THE NATURE AND TREATMENT OF CANCER

BY JOHN A. SHAW-MACKENZIE, M.D.Lond.

"There is a charm as well as an attraction about this work, inasmuch as it deals with many hitherto but little known physiological processes. . . . How many practising physicians and surgeons, for example, ever heard of trypsin before the author brought it under the notice of the profession, and proved its therapeutic value, besides showing its action on glycogen?"—THE MEDICAL PRESS AND CIRCULAR.

London : Bailliere, Tindall & Cox, 8 Henrietta Street, Covent Garden.

NOW READY. SIXTH EDITION, 587 pages, with 249 Illustrations
Royal 8vo. Price 15s. net.

Diseases and Injuries of the Eye,

WITH THEIR MEDICAL AND SURGICAL TREATMENT.

By GEORGE LAWSON, F.R.C.S.
Revised and Re-written by ARNOLD LAWSON, F.R.C.S.

London : Smith, Elder & Co., 15 Waterloo Place, S.W.

SECOND EDITION, with Illustrations, royal 8vo, 10s. 6d.

The Treatment of Lateral Curvature
OF THE SPINE.

By BERNARD ROTH, F.R.C.S.

"In speaking of the first edition we expressed the hope that this book would do something to check the unscientific and often disastrous treatment of lateral curvature of the spine by spinal supports and prolonged rest, and this new edition is even better calculated to show the good results which may be obtained in lateral curvature by posture and exercise."—LANCET.

"There can be no doubt that good work has been done by the author by his strong advocacy of the more rational method of treating lateral curvature of the spine by exercises."—BRITISH MEDICAL JOURNAL.

London : H. K. Lewis, 136 Gower Street, W.C.

Just Published. Pp. viii. + 509. Price 10s. 6d. net.
Second Edition. Enlarged and Re-written.

LECTURES ON
DISEASES OF THE LUNGS.

By JAMES ALEXANDER LINDSAY, M.D., F.R.C.P.,
Professor of Medicine, Queen's College, Belfast ; Examiner in Medicine in the Royal University of Ireland.

"We offer the author our congratulations upon having written a valuable and instructive work."—*Lancet.*

"Bears on every page the stamp of practical experience."—*British Medical Journal.*

"We commend these lectures to the study of both students and practitioners."—*The Practitioner.*

By W. ARBUTHNOT LANE, M.S.

Cleft Palate and Hare Lip.

New Edition, in large clear type, demy 4to, 5s.

"Mr. Lane makes out a clear case for early and almost immediate operation. To sum up : Mr. Lane has absolutely proved his contention, and rendered it quite clear that early operation is the right course on every ground, developmental and otherwise ; and, further, that delay in performing staphylorrhaphy until the third or sixth year is fraught with most harmful results, and should not be permitted."—*British Medical Journal*, Jan. 27th, 1906.

Operative Treatment of Fractures.

CHÂTEL=GUYON.

Auvergne, France.
6½ hours from Paris.

The most Important Thermal Station in France except Vichy and Aix-les-Bains.

CHÂTEL-GUYON is situated at the foot of the Dome Mountains, near Clermont-Ferrand. Its Mineral Waters are celebrated for their efficacy in all **MALADIES** of the **INTESTINES** and of the annexed organs. It is the most renowned Thermal Station in the World for the **CURE** of **CONSTIPATION** and **ENTERITIS.**

Its Waters are also specially indicated for **APPENDICITIS, TYPHLITIS, ABDOMINAL INFECTIONS,** and all **ARTHRITIC TROUBLES** arising from sluggish nutrition.

The Mineral Waters of **CHÂTEL-GUYON** are Carbo-Gaseous, and have a flow of Five Million Litres every 24 hours. Their average Temperature is from 82° to 95° Fahrenheit. **They contain Free Carbonic Acid, Chlorides of Magnesium and Sodium, and mixed Bicarbonates.**

THEIR CHIEF CHARACTERISTIC IS CHLORIDE OF MAGNESIUM.

Two Large **ESTABLISHMENTS,** with running-water Baths as at Nauheim, and the latest **Hydrotherapeutic** Appliances, **Casino, Theatre, Music Kiosks, Excellent Hotels,** Numerous **Villas, Picturesque Mountain Excursions.**

CHATEL-GUYON
Comprimés
Pastilles
Sondes
DE
Chatel-Guyon

FOR HOME TREATMENT, the

CHÂTELGUYON-GUBLER WATER

Unequalled for Disinfection of the **INTESTINE** and its annexes, and for Regulating **DIGESTION.**

READY TO-DAY

In the "University Series" of Manuals

THE SECOND VOLUME, COMPLETING

BUCHANAN'S ANATOMY:

Systematic and Practical, including Embryology.

1572 Pages in Two Volumes.

631 Illustrations mostly Original and in Several Colours.

Price 12/6 each net.

"It is written by one who has for many years been engaged in teaching the subject. Dr. A. M. Buchanan's name is a household word with many generations of students, both as a teacher of, and examiner in anatomy. The volume might be described as a combination of atlas, dissector's manual, and systematic description; and the popularity it is sure to attain will be entirely the fruit of its merits." —GLASGOW MEDICAL JOURNAL.

"It is marked by a refinement of style, an exactitude of expression, a beautiful simplicity of arrangement, a fulness of material knowledge, and an unrivalled lucidity of language worthy of a great master...............It is an anatomical treatise which will be treasured by the student as an easy highway to a place of honour on the examination list." —HOPITAL.

This work combines a Manual of Practical Anatomy with a Text-book of Systematic Anatomy, thus forming a complete treatise on the whole subject.

Libraries furnished. Catalogues post free on application.

HOMMEL'S Hæmatogen

CONTAINS NEITHER ALCOHOL NOR ANTISEPTICS

A combination of 80 parts purified and concentrated Hæmoglobin with 20 parts chemically pure Glycerine and Aromatic Flavouring.

The best of all the existing preparations of Hæmoglobin. More efficacious than Cod-Liver Oil or the ordinary manufactured preparations of Iron. Very strengthening both for Children and Adults. An energetic Blood Former. Increases the Appetite. Aids Digestion.

☞ Extremely useful in **Rickets, Scrofula, General Debility, Anæmia, Weak Heart, Neurasthenia,** and Convalescence from illness such as **Pneumonia** or **Influenza.**

☞ Unsurpassed as a **Strengthening Restorative in Diseases of the Lungs.** Has a very agreeable taste, and is taken with the utmost relish even by Children.

FREE FROM BACTERIAL GROWTH. UNCHANGED BY KEEPING.

These important qualities are guaranteed by using the highest permissible temperature in the process of manufacture (130° to 140° Fahr. for 24 hours). No guarantee of this description is possible for preparations made by a cold process with ether.

☞ **In prescribing, always state "HOMMEL'S" Hæmatogen as spurious imitations are offered.** ☜

ONLY SUPPLIED IN FLUID, NOT IN CAPSULES OR OTHER FORMS.

Infants - - Take from Half to One Teaspoonful twice a day in milk.
Children - „ One or Two Dessertspoonfuls daily, either pure or mixed with any convenient liquid.
Adults - - „ One Tablespoonful twice a day **before** the two principal meals.

☞ **SAMPLES AND LITERATURE,** *gratis and carriage paid, on application.*

Second Edition, with 39 Plates and 79 Illustrations. Price 15s. net.

Diseases of the Stomach and their Surgical Treatment.

By A. W. MAYO ROBSON, F.R.C.S.,
Hunterian Professor of Surgery in the Royal College of Surgeons of England, and
By G. A. MOYNIHAN, M.B., M.S.Lond., F.R.C.S.Eng.,
Senior Assistant Surgeon, Leeds General Infirmary; Examiner in the Royal College of Surgeons, England.

"The whole work has undergone a most careful revision. Indeed the greater part of it has been rewritten, for where our knowledge has so greatly increased, the form and method of the first edition seemed inappropriate, and it was easier and more satisfactory to rewrite than to modify."—*Extract from Preface.*

London: Baillière, Tindall & Cox, 8 Henrietta Street, Covent Garden.

NOW READY. Pp. xii. + 300. With 184 Illustrations. Price 6s.

STUDENT'S HANDBOOK OF OPERATIVE SURGERY.

By W. I. DE COURCEY WHEELER, B.A., M.D., F.R.C.S.,
Surgeon to Mercers Hospital; Ex-Demonstrator of Anatomy, Trinity College, Dublin.

London: Baillière, Tindall & Cox, 8 Henrietta Street, Covent Garden.

SAL HEPATICA

EFFERVESCENT SALINE LAXATIVE.
URIC ACID SOLVENT.

A combination of the Tonic, Alterative and Laxative Salts similar to the celebrated Bitter Waters of Europe, fortified by the addition of Lithia and Sodium Phosphate.

It stimulates the liver, tones intestinal glands, purifies alimentary tract, improves digestion, assimilation, and metabolism.

Especially valuable in **Rheumatism, Gout, Bilious Attacks, Constipation.**

Most efficient in eliminating toxic products from intestinal tract or blood, and correcting vicious or impaired functions.

Write for free sample.

In all disorders of the respiratory tract in which inflammation
or cough is a conspicuous factor, incomparably beneficial
results can be secured by the administration of

Glyco-Heroin (Smith)

The preparation instantly diminishes cough,
augments expulsion of secretions, dispels
oppressive sense of suffocation, restores
regular, pain-free respiration and subdues
inflammation of the air passages.

The marked analgesic, antispasmodic, balsamic, expectorant,
mucus-modifying and inflammation-allaying properties of
GLYCO-HEROIN (SMITH) explain the curative
action of the Preparation in the treatment of

**Coughs, Bronchitis, Pneumonia, Laryngitis,
Pulmonary Phthisis, Asthma, Whooping Cough**

and the various disorders of the breathing passages.

GLYCO-HEROIN (SMITH) is admittedly the ideal heroin
product. It is superior to preparations containing codeine
or morphine, in that it is vastly more potent and does
not beget the bye-effects common to those drugs.

**DOSE.—The adult dose is one teaspoonful, repeated
every two or three hours. For children of more than
three years of age, the dose is from five to ten drops.**

Samples and exhaustive literature bearing upon the preparation
will be sent, post paid, on request.

Infantile Diarrhœa

During summer, Diarrhœa and kindred disorders among Infants are largely due to the use of infected cow's milk.

The "Allenburys" Milk Foods

are absolutely free from all harmful bacteria, and are made ready for use with boiled water.

The Foods are easily digested and assimilated, and contain both fat and proteids in similar relative proportions to those found in human milk. They are capable also of further modification, when desired, to suit the most delicate Infants from birth.

Allenburys Feeder

The "Allenburys" Milk Food No. 1.

FROM BIRTH TO 3 MONTHS.

This closely approximates in composition to human milk. It keeps thoroughly well, is easily prepared, the addition of hot water only being necessary.

The "Allenburys" Milk Food No. 2.

FROM 3 TO 6 MONTHS.

Is similar to the Milk Food No. 1, with the addition of a small amount of soluble phosphates and albuminoids.

The "Allenburys" Malted Food No. 3.

FROM 6 MONTHS AND UPWARDS.

Is a partially digested farinaceous food, and requires the addition of boiled cow's milk and water.

A full descriptive pamphlet and samples will be sent on request.

IN THE TREATMENT OF

ANÆMIA, NEURASTHENIA, BRONCHITIS, INFLUENZA, PULMONARY TUBERCULOSIS, AND WASTING DISEASES OF CHILDHOOD, AND DURING CONVALESCENCE FROM EXHAUSTING DISEASES,

THE PHYSICIAN OF MANY YEARS' EXPERIENCE

KNOWS THAT, TO OBTAIN IMMEDIATE RESULTS, THERE IS NO REMEDY THAT POSSESSES THE POWER TO ALTER DISORDERED FUNCTIONS LIKE

"Fellows' Syrup of Hypophosphites"

MANY A TEXT-BOOK ON RESPIRATORY DISEASES SPECIFICALLY MENTIONS THIS PREPARATION AS BEING OF STERLING WORTH.

TRY IT, AND PROVE THESE FACTS.

SPECIAL NOTE.—Fellows' Syrup is never sold in bulk, but is dispensed in bottles containing 8 oz. and 15 oz.

THIS PREPARATION MAY BE OBTAINED AT ALL CHEMISTS AND PHARMACISTS THROUGHOUT THE UNITED KINGDOM.

FORMAMINT

An Excellent Antiseptic and Prophylactic in Diseases of the Throat and Mouth

EFFICIENT SUBSTITUTE FOR GARGLES.

COMPOSITION: Vide Article on "Oral Sepsis" in *The Lancet*, Oct. 20th, 1906.

"A chemical combination of Formic Aldehyde and Lactose put up in the form of a compressed tablet."

"A non-toxic and trustworthy antiseptic in all ages, differing entirely from simple solutions of formic aldehyde in nature and in action being much more powerful, devoid of any irritating properties, and which on solution by the saliva sets free that disinfectant in a nascent form."

INDICATIONS: in all conditions of **SEPTIC SORE THROAT,** as **TONSILLITIS**—Simple, Septic and Follicular—**DIPHTHERIA, SCARLET FEVER, MEASLES, THRUSH,** etc.

"In ten cases of **Diphtheria** the treatment by Formamint Tablets was employed as a substitute for local treatment by disinfectant gargles, and in some of the milder cases anti-toxin was dispensed with. In all cases the improvement was rapid."—(*British Medical Journal*, January 13th, 1906, Epitome, page 8.)

"A proved antiseptic and bactericide, non-toxic in action, far more efficient than gargles or mouth washes, particularly suitable for children and entails no pain, and its portability is of considerable convenience."—*Medical Magazine*, March, 1907).

ORAL SEPSIS.

'Eumenthol Jujubes'

(HUDSON.)

Made in Australia.

A Gum pastille containing the active constituents of well-known Antiseptics:—Eucalyptus Globulus (a well rectified oil free from Aldehydes, especially Valeric Aldehyde, which make themselves unpleasantly noticeable in crude oils by the tendency to produce coughing), Thymus Vulg., Pinus Sylvestris, Mentha Arv., with Benzo-borate of Sodium, &c., and exhibit the antiseptic properties in a fragrant and efficient form. Non-coagulant antiseptic and prophylactic, reducing sensibility of mucous membrane.

The LANCET says:—"In the experiments tried the Jujube proved to be effective bactericidally as is Creosote."

Mr. W. A. DIXON, F.I.C., F.C.S., Public Analyst of Sydney, after making exhaustive tests, says:—"There is no doubt but that 'Eumenthol' Jujubes have a wonderful effect in the destruction of bacteria and preventing their growth. . . . . . I have made a comparative test of 'Eumenthol' Jujubes and Creosote, and find that there is little difference in their bactericidal action."

The PRACTITIONER says:—"Are also useful in tonsilitis, pharyngitis and similar ailments."

ST. PATRICK'S HOSPITAL FOR MENTAL DISEASES.

THE GOVERNORS OF

ST. PATRICK'S HOSPITAL, DUBLIN

(FOUNDED BY DEAN SWIFT IN 1745),

Wish to announce that they have acquired a large property, in accordance with their Royal Charter (200 acres), and established a Private Asylum in connection with the Hospitals at Lucan, for the reception of patients of both sexes suffering from Mental Disease.

A NEW VILLA has been erected at Lucan for the accommodation of a limited number of gentlemen, and the entire establishment has been lighted by electricity.

The parent institution in Dublin continues its curative work, has undergone almost entire reconstruction, receives both male and female patients, and its recovery rate is very satisfactory. The Governors are anxious that the Medical Profession should be acquainted with the work of this historic institution, which has been devoted for over a century and a half to the reception and curative treatment of the insane of Ireland.

Urgent cases can be admitted by direct application to the Medical Superintendent.

For further particulars, forms of admission, &c., apply to the REGISTRAR, St. Patrick's Hospital, James Street, Dublin.

PRIVATE ASYLUMS,

Co. DUBLIN.

For Patients of the Upper Class suffering from Mental and Nervous Diseases, and the Abuse of Drugs. Established 1825.

HAMPSTEAD,	HIGHFIELD,
GLASNEVIN, FOR GENTLEMEN.	DRUMCONDRA, FOR LADIES.

Telephone No. 1082.

These Hospitals are built on the Villa System, and there are also Cottages on the demesne (154 acres), which is 100 feet above the sea-level, and commands an extensive view of the Dublin Mountains and Bay.

Voluntary Patients admitted without Medical Certificates.

For further information apply for illustrated prospectus, &c., to the Resident Medical Superintendents, Dr. HENRY MARCUS EUSTACE, Highfield, Drumcondra, or Dr. WILLIAM NEILSON EUSTACE, Hampstead, Glasnevin; or at the office, 41 Grafton Street, Dublin. Telephone 196. On Mondays, Wednesdays and Fridays, from 2 to 3 p.m.

THE ONLY ASEPTIC FEEDER MADE IS THE ROTUNDA FEEDING BOTTLE

It is simple—only a pure rubber teat and bottle—no valve. It is safe—for it can be sterilised. It is cheap—6d.

Can be had wholesale from any Druggists' Sundry House, or from

LEONARD & CO., Chemists, Dublin & Belfast.

Leonard's Rotunda Tissue, 1/- per lb.

Leonard's Clinical Thermometers, 1/- each.

STRETTON HOUSE,

Church-Stretton, Shropshire.

A Private HOME for the treatment of Gentlemen suffering from Mental diseases. Bracing hill country. See "Medical Directory," p. 1958.

Apply to Medical Superintendent. Telephone: 10 P.O. Church-Stretton.

THE RETREAT PRIVATE ASYLUM,

Near ARMAGH.

(ESTABLISHED 1824.)

Licensed for the reception of ladies and gentlemen of the upper and middle classes suffering from

MENTAL AND NERVOUS DISEASES.

(Voluntary Boarders and Inebriates admitted.) This establishment has lately undergone many structural alterations and improvements, and the walks and grounds are extensive and picturesque.

Great care and attention are bestowed upon the patients, outdoor and indoor games and regular carriage exercise being provided.

Golf links have recently been added.

For further information apply to the Medical Superintendent, Dr. J. GOWER ALLEN, J. P., or Mr. JOSEPH ALLEN, Clonallen, Armagh.

STEWART INSTITUTION

FOR IMBECILE CHILDREN, AND HOSPITAL FOR MENTAL DISEASES, Palmerston, Chapelizod, co. Dublin.

This institution receives imbecile children from all parts of Ireland free, or by partial payment, by election. Full payment cases at moderate rates. One vote for every 10s. 6d. subscribed annually. A life vote for £5 5s. donation.

The Hospital for Mental Diseases—a separate establishment—receives lady and gentleman patients from £50 per annum upwards according to accommodation required. Management fully up-to-date in all particulars. Beautiful situation. Best modern sanitation. Fine demesne with necessary privacy. Voluntary boarders received.

Resident Medical Superintendent: Dr. F. E. Rainsford. All particulars from Secretary at Office, 40 Molesworth Street, Dublin.

DUBLIN.

FARNHAM HOUSE

For Gentlemen; MARYVILLE for Ladies.

AT FINGLAS, NEAR DUBLIN.

Private Hospitals for Patients of the Upper Classes SUFFERING FROM

NERVOUS AND MENTAL DISEASES, ALCOHOLISM, ETC.

Telephone No. 1470. Telegrams: "Dawson, Finglas."

Consulting Rooms: 41 Upper Fitzwilliam Street, Dublin.

These establishments, which are healthily situated in pretty grounds upwards of 46 acres in extent, provide modern medical curative and palliative treatment on moderate terms. Voluntary boarders admitted without certificates. Large staff maintained. Up-to-date sanitation.

Prospectuses, forms, &c., on application to the Resident Medical Superintendent, W. R. DAWSON, M.D., F.R.C.P.I., at the Institution, or at the Consulting Rooms from 3 to 5 p.m. on Mondays, Wednesdays, and Fridays, or by appointment.

HARTFIELD HOUSE,

DRUMCONDRA, DUBLIN, FOR GENTLEMEN.

Established in 1848, under the Patronage of the Most Rev. Dr. Murray, Archbishop of Dublin. Telephone: No. 334.

Tele. Address: "PROPRIETOR, HARTFIELD HOUSE, DRUMCONDRA."

VERVILLE, CLONTARF,

NEAR DUBLIN, FOR LADIES.

Established in 1857.

Telegraphic Address: "PROPRIETOR, VERVILLE, CLONTARF."

These Establishments are for the treatment and care of Ladies and Gentlemen suffering from mental disturbance or mental disease.

A limited number of Patients suffering from ailments arising out of the continuous abuse of alcohol or drugs are received as voluntary patients, without medical certificates.

A Catholic Chaplain visits regularly, and celebrates Mass on Sundays and Holy days.

Visiting Physician: Dr. BURKE SAVAGE, Rutland Square, Dublin

For further particulars, apply to Dr. LYNCH, or to J. J. MAGRATH Superintendent.

Dr. J. Collis Browne's
CHLORODYNE
THE ORIGINAL AND ONLY GENUINE.

From Symes & Co., Chemists, Medical Hall, Simla, January 5th, 1880.
To J. T. Davenport, Esq., London,

Dear Sir,—Have the goodness to furnish us with your best quotations for Dr. J. Collis Browne's Chlorodyne. We embrace this opportunity of congratulating you upon the widespread reputation this justly esteemed medicine has earned for itself, not only in Hindostan, but all over the East. The other brands are now relegated to the native bazaars, and judging from their sale, we fancy their sojourn there will be but evanescent. We could multiply instances *ad infinitum* of the extraordinary efficacy of Dr. Collis Browne's Chlorodyne in Diarrhœa and Dysentery, Spasms, Cramps, Neuralgia, the Vomiting of Pregnancy, and as a general sedative, that have occurred under our personal observation during many years. In Choleraic Diarrhœa, and even in the more terrible forms of Cholera itself, we have witnessed its surprisingly controlling power. We have never used any other form of this medicine than Collis Browne's from a firm conviction that it is decidedly the best, and also from a sense of duty we owe to the profession and the public, as we are of opinion that the substitution of any other than Collis Browne's is a deliberate breach of faith on the part of the chemist to prescriber and patient alike.

We are, Sir, faithfully yours, SYMES & CO.,
His Excellency the Viceroy's Chemists.

WHEN PRESCRIBING CHLORODYNE, REMEMBER TO ADD THE NAME OF "DR. J. COLLIS BROWNE," OTHERWISE A SUBSTITUTE MAY BE USED, TO THE DETRIMENT OF THE PATIENT.

TAMAR INDIEN GRILLON.

A Laxative, Refreshing, and Medicated Fruit Lozenge.
VERY AGREEABLE TO TAKE, AND NEVER CAUSING IRRITATION.

Its physiological action assures the immediate relief and . . . effectual cure of . . . . . . **CONSTIPATION,**

HÆMORRHOIDS, BILE, HEADACHE, LOSS OF APPETITE. AND INTESTINAL OBSTRUCTIONS

By augmenting the peristaltic movement of the intestine without producing undue secretion of the liquids. Unlike pills and the usual purgatives, it does not predispose to intestinal sluggishness; and the same dose always produces the same effect—that is to say, never needs increasing.

It is recommended by the most eminent physicians of Paris, notably Drs. Belin and Tardieu, who prescribe it constantly for the above complaints, and with the most marked success.

Wholesale—London: E. GRILLON, 67 Southwark Bridge Road, S.E.
Sold by all Chemists and Druggists, 2s. 6d. a box, stamp included.

June 11th, 1907. STEWART JOHNSON, Secretary.

ROYAL COLLEGE OF SURGEONS
IN IRELAND.
CARMICHAEL PRIZE ESSAY.

The late Richard Carmichael, Esq., having bequeathed to the College a sum of money for the purpose of founding Prizes for Essays upon certain subjects specified by him, the President and Council hereby give notice that, on the first Thursday in November in the year 1908, they will proceed to adjudge a prize of One Hundred and Twenty Pounds for the best Essay that may be presented to them in accordance with the following instructions prescribed by Mr. Carmichael.

1st. "The state of the Medical Profession in its different departments of Physic, Surgery, and Pharmacy, in Great Britain and Ireland, at the time of the writing of these Prize Essays."

2nd. "The state of the Hospitals and Schools of Medicine, Surgery, and Pharmacy."

3rd. "The state and mode of examination, or of testing the qualifications of Candidates of the different Licensing Colleges or Corporations of Medicine, Surgery, and Pharmacy."

"Under these heads the authors will be pleased to make such suggestions as may occur to them respecting the improvement of the profession, with the view of rendering it more useful to the public, and a more respectable body than it is at present. In these suggestions the authors will be pleased to consider the preliminary and moral education of Medical and Surgical Students, as well as the mode of conducting their professional studies."

"In considering the third head, or mode of testing the qualifications of candidates by the licensing bodies, the authors will please to consider the most practical mode of rendering the examination as demonstrative as possible—*i.e.*, in Anatomy, by having the dead subject placed before the candidate; in Chemistry, Botany, and Pharmacy, specimens of minerals, plants, and pharmaceutical preparations placed before him; and in the practice of Physic and Surgery, the candidate to be placed before the patients in the wards of an hospital as the testator is certain that this will afford the most certain and only true mode of ascertaining the qualifications of candidates."

Each Essay is to be distinguished by a device or motto, and accompanied by a sealed packet, containing the name and address of the author, also distinguished by the same device or motto. The Essays are to be lodged at the College on or before the first day of July, 1908.

No Essay shall exceed 65,000 words in length, and all quotations and extracts from any published work, pamphlet or paper, shall be by reference merely to the volume and page on which the passage desired to be quoted is to be found.

The President and Council will not consider themselves bound to award the Prizes should any of the Essays not appear to them to possess sufficient merit.

By order of the Council,
JOHN BARTON, F.R.C.S.,
Secretary of the Council.
Dublin, June 19, 1907.
